Description	<ul style="list-style-type: none">• Response is measured as on/off or true/false• Outcomes are measured in the offspring of exposed, pregnant animals• BMDS can only model positive dose-response trends, where incidence increases with dose
Example Endpoints	<ul style="list-style-type: none">• Structural abnormalities – malformations (e.g., cleft palate) or variations (ossification changes)• Mortality – resorptions (early mortality) or fetal death (late mortality)
Model Inputs	<ul style="list-style-type: none">• Dose• Individual animal (i.e., dam) data – number of offspring experiencing the effect per exposed dam

BMD Analysis – Six Steps

- **BMR should be near the low end of the observable range of increased risks in a bioassay**
- **BMRs that are too low can impart high model dependence, i.e., different models have different shapes in the extreme low dose area and will provide different BMDL estimates.**

- **Although an excess risk of 10% is usually a standard BMR for dichotomous data, an excess risk of 5% approximates the NOAEL for most developmental studies.**
- **In a series of papers (Faustman et al., 1994; Allen et al., 1994a,b), it was shown that the BMDL for 5% extra risk corresponded on average with NOAELs identified from a large developmental toxicity database**
- **Support for using a BMR of 5% for developmental data**
 - Developmental studies provide increased statistical power compared to regular toxicity studies due the increase in sample size (i.e., use of pups as the observational subject)
 - Developmental effects are often considered to be severe, or sometimes frank (i.e., fetal mortality)

- **For dichotomous data, BMRs are expressed as:**
 - **Added risk** – $AR(d) = P(d) - P(0)$
 - **Extra risk** – $ER(d) = [P(d) - P(0)]/[1 - P(0)]$
- **Extra risk is recommended by the IRIS, and is used in IRIS risk assessments.**

Added vs. Extra Risk

10% Added Risk

$$0.10 = P(d) - P(0) ; \text{ if } P(0) = .50$$

$$P(d) = 0.10 + P(0) = 0.10 + 0.50 = \mathbf{0.60}$$

10% Extra Risk

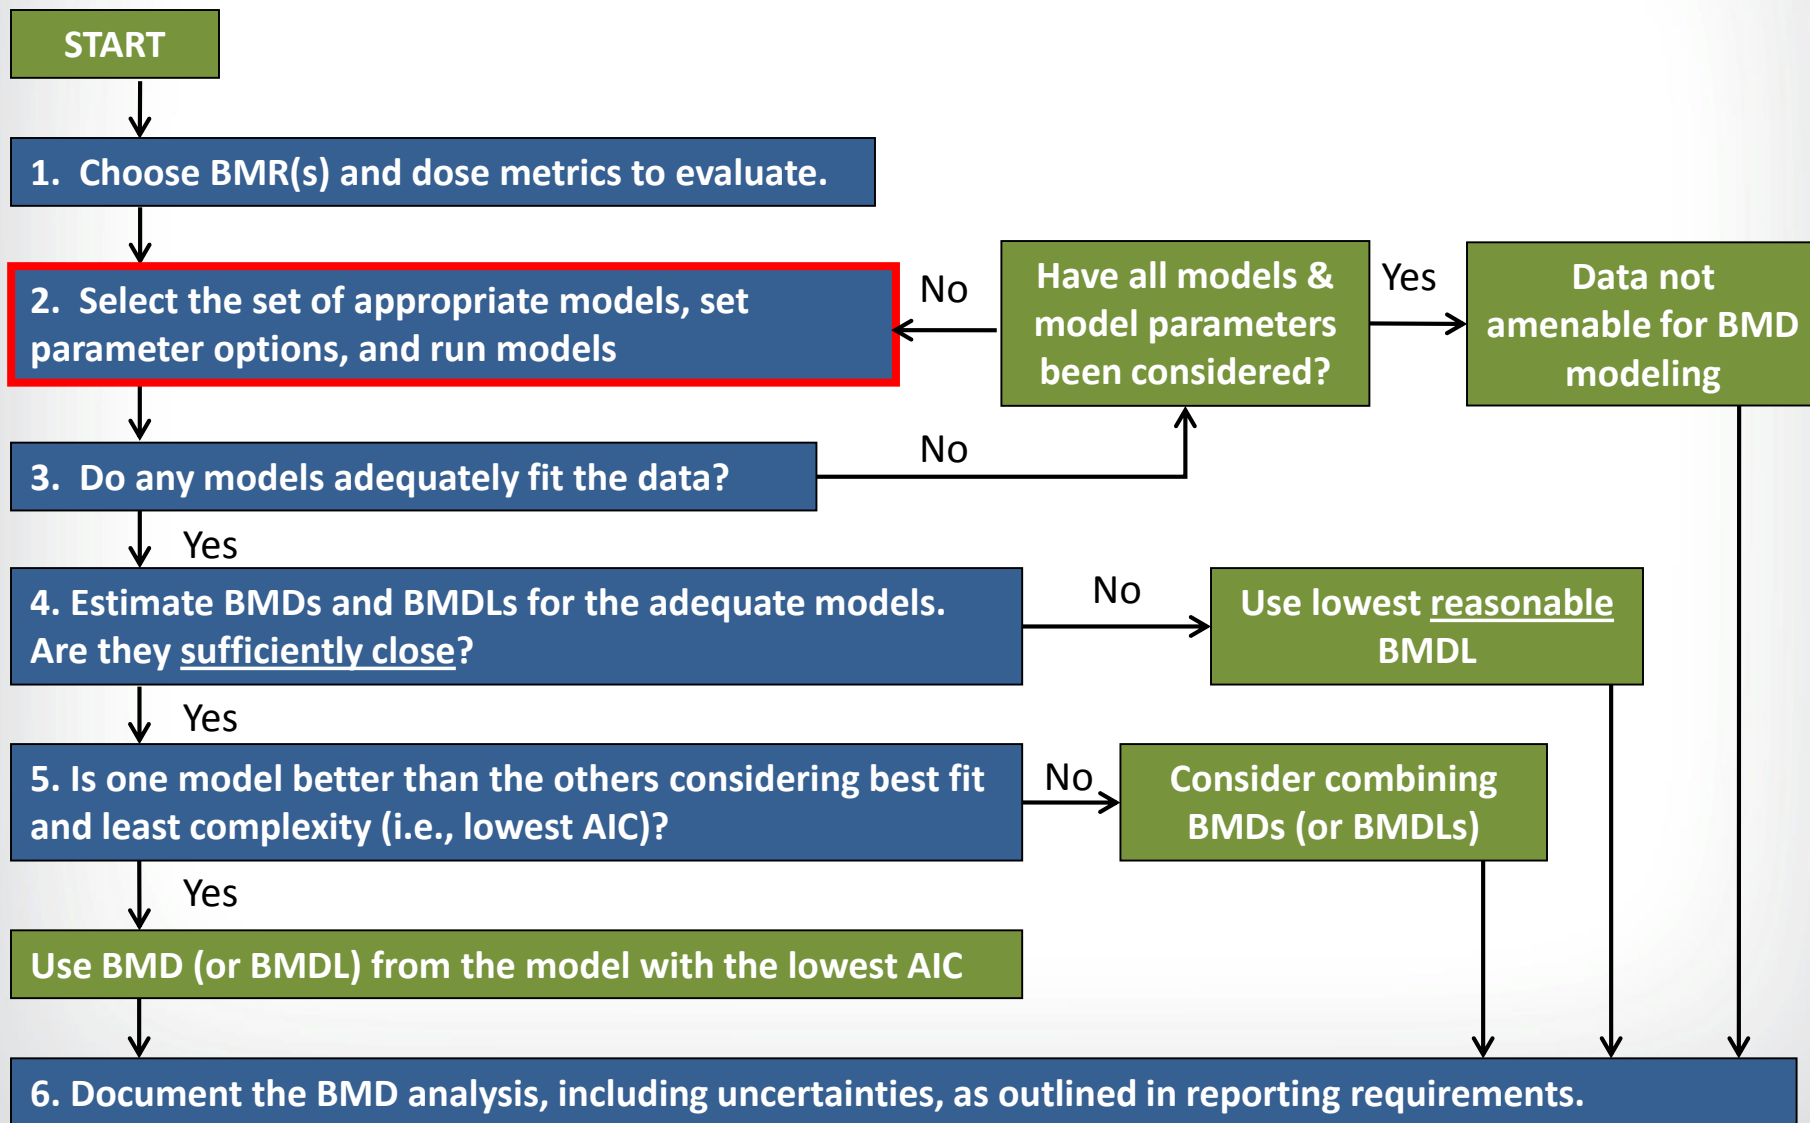

$$0.10 = [P(d) - P(0)] / [1 - P(0)]; \text{ if } P(0) = .50$$

$$P(d) = 0.10 \times [1 - P(0)] + P(0) = (0.10 \times 0.50) + 0.50 = \mathbf{0.55}$$

The dose will be lower for a 10% Extra risk than for a 10% Added risk if $P(0) > 0$

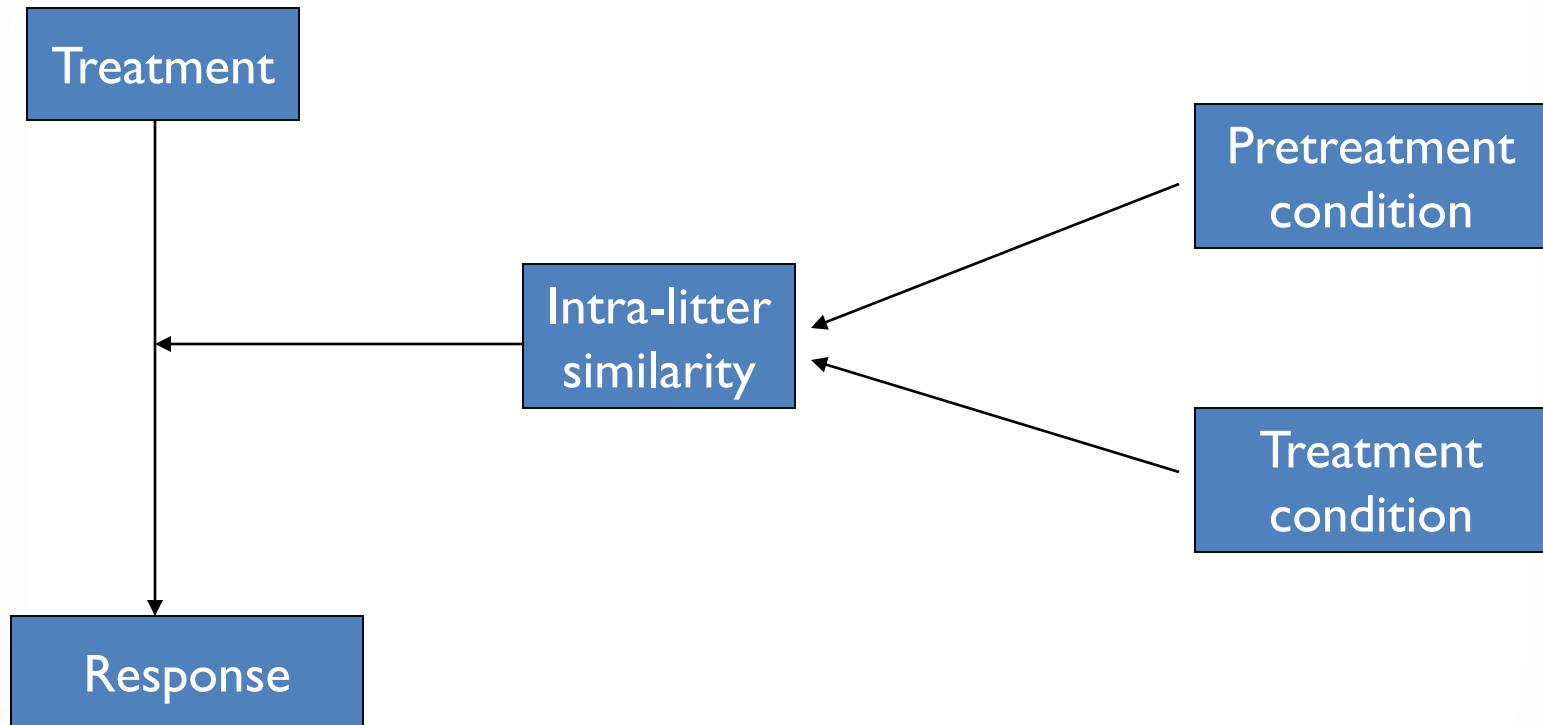

BMD Analysis – Six Steps

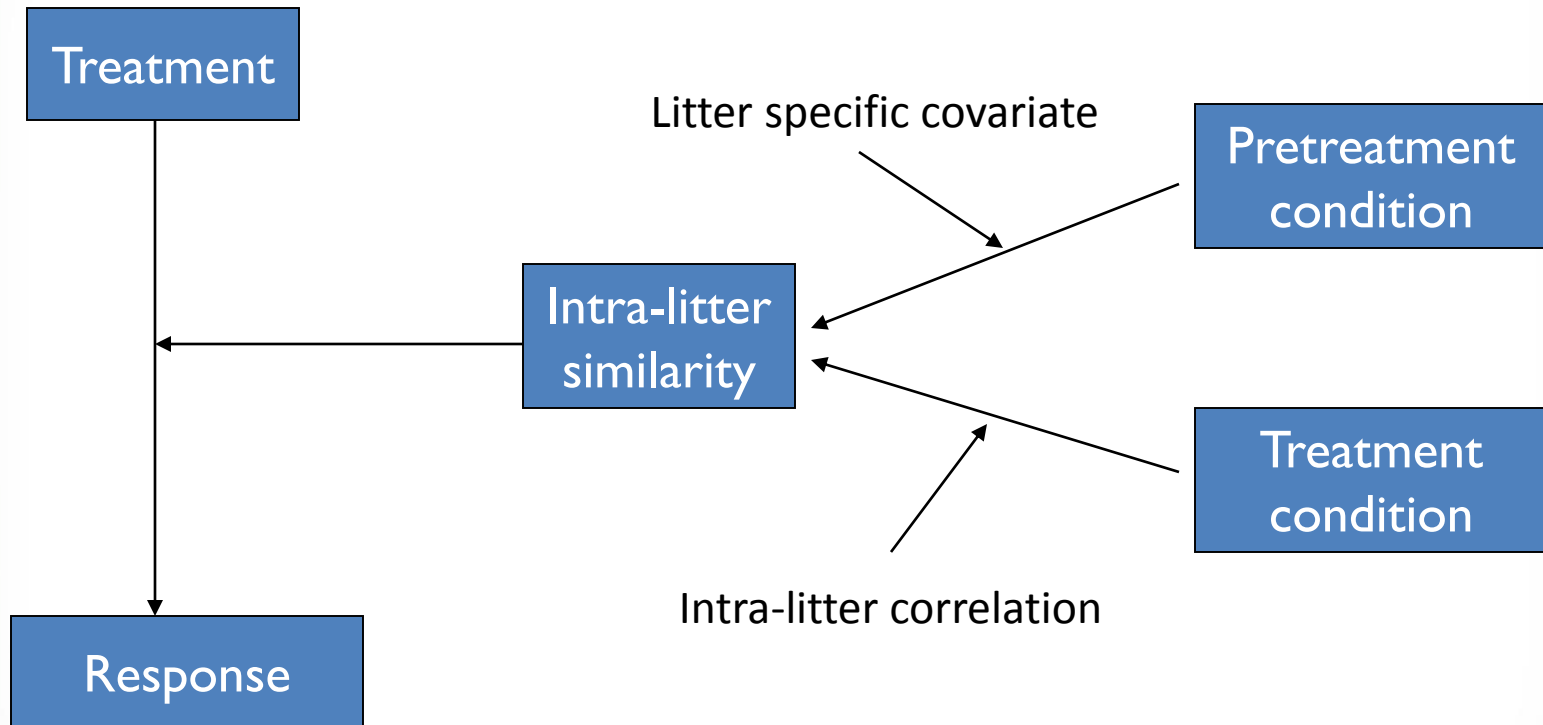

Model name	Functional form	Notes
Nested Logistic ^a	$\frac{\alpha + \theta_1 r_{ij} + [1 - \alpha - \theta_1 r_{ij}]}{(1 + \exp[-\beta - \theta_2 r_{ij} - \rho * \ln(X)])}$	r_{ij} is the litter specific covariate for the j^{th} litter in the i^{th} dose group, there are g intra-litter correlation coefficients , $0 < \Phi_i < 1$ ($i = 1, \dots, g$)
NCTR	$1 - \exp[-(\alpha + \theta_1 [r_{ij} - r_m]) - (\beta + \theta_2 [r_{ij} - r_m]) * dose_\rho]$	r_{ij} is the litter specific covariate for the j^{th} litter in the i^{th} dose group, and r_m is the overall mean for the litter-specific covariate, there are g intra-litter correlation coefficients , $0 < \Phi_i < 1$ ($i = 1, \dots, g$)
Rai and van Ryzin	$[1 - \exp(-\alpha - \beta(dose_\rho))] * \exp(-(\theta_1 + \theta_2 dose) * r_{ij})$	r_{ij} is the litter specific covariate for the j^{th} litter in the i^{th} dose group, there are g intra-litter correlation coefficients , $0 < \Phi_i < 1$ ($i = 1, \dots, g$)

^aThe nested Logistic model is the Log-logistic model modified to include a litter-specific covariate. Log-logistic model form: $\frac{\gamma + (1 - \gamma)}{1 + \exp\{-[\alpha + \beta \ln(X)]\}}$

- **It is usual for the responses of pups in the same litter to be more similar to each other than to the responses of pups in different litters**
 - This is typically called “intra-litter similarity” or “litter effects”
- **Models for nested dichotomous data incorporate two parameters to address this issue**
 - Litter specific covariate (θ coefficients)
 - Intra-litter correlation (Φ coefficients)

- **A litter specific covariate (θ coefficients) takes into account the condition of the exposed dam prior to the onset of dosing/exposure.**
- **The pre-treatment condition of the dam should account for some of the observed “litter effect”**
- **The litter specific covariate should NOT be affected by treatment**
- **Commonly used litter specific covariates include:**
 - Litter size
 - Dam weight
 - Implantation sites

Rat Developmental Milestones

- **Implantation sites**
 - In a normal guideline developmental toxicity study, where dosing begins after implantation takes place, the number implantation sites is the preferred litter specific covariate
 - However, these data are not reported in some toxicity studies
- **Litter size**
 - Litter size is an appropriate litter specific covariate as long as there are not treatment-related resorptions or prenatal deaths

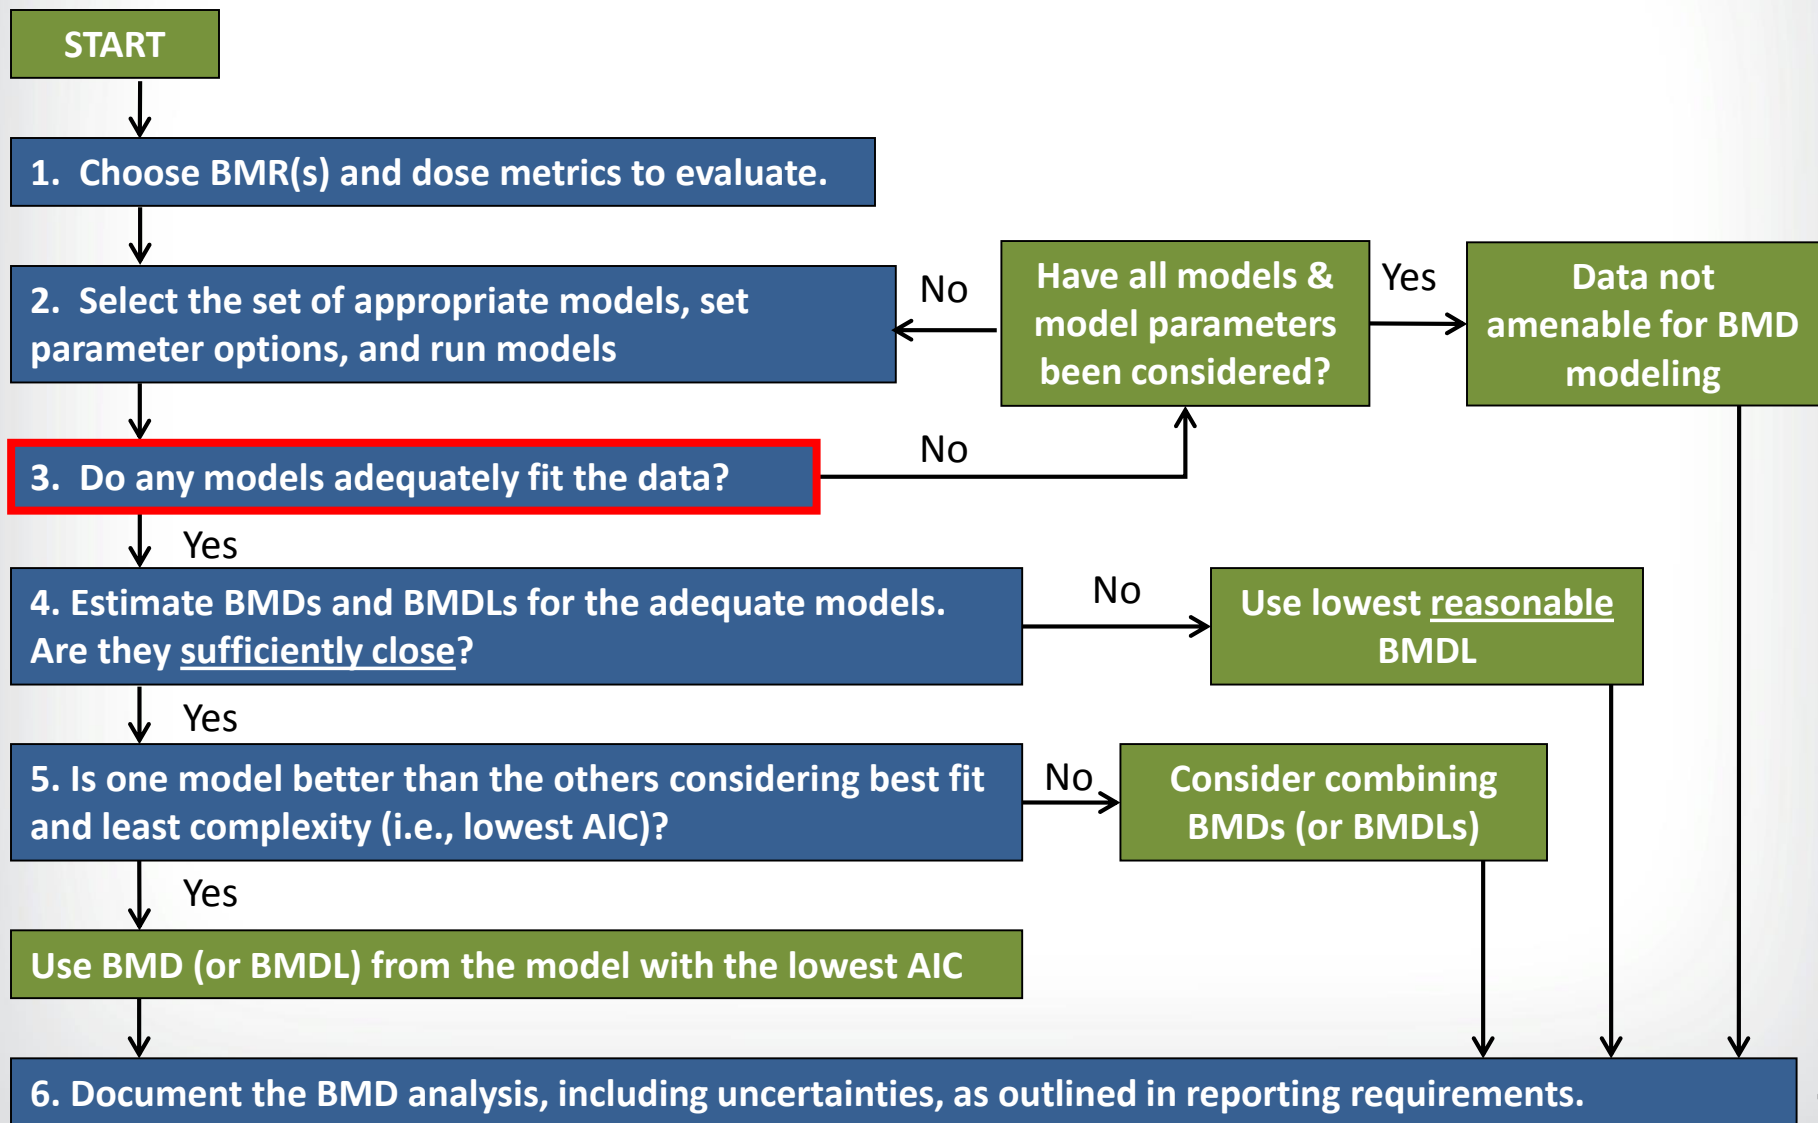

- **The litter specific covariate should only be used when ALL of the following 3 criteria are met:**
 - The chosen litter specific covariate is not affected by treatment
 - θ coefficients are estimated by BMDS to be non-zero (currently, the software does not estimate coefficient standard errors, so some judgement is required when making this determination)
 - If the model estimates the θ coefficients to be EXACTLY 0, the modeling results (including AIC) should be the same as when running the model with the litter specific covariate turned off.
 - When the litter specific covariate is included in the modeling scheme, the model fit becomes better (e.g., per AIC or scaled residual comparison)
- **NOTE: regardless of whether an appropriate litter specific covariate can be identified, the modeled dataset MUST contain “covariate” data (even if it’s dummy data)**

- **The intra-litter correlation statistically describes the similarity of responses among pups in the same litter**
- **Intra-litter correlation should only be used when **BOTH** of the following 2 criteria are met:**
 - Φ coefficients are estimated by BMDS to be non-zero (currently, the software does not estimate coefficient standard errors, so some judgement is required when making this determination)
 - When the intra-litter correlation is included in the modeling scheme, the model fit becomes better (e.g., per AIC or scaled residual comparison)
- **When intra-litter correlation is used, if the range of the scaled residuals for the litters with the same litter specific covariate is not reduced, consult a statistician to determine a course of action**

- **For a single dataset, run the desired nested dichotomous model 4 times (assuming there is a covariate appropriate for the litter specific covariate):**
 - Litter specific covariate = -, intra-litter covariate = +
 - Litter specific covariate = + intra-litter covariate = -
 - Litter specific covariate = -, intra-litter covariate = +
 - Litter specific covariate = +, intra-litter covariate = +
- **Applying the criteria in the previous slides, final model selection can be made based on global goodness-of-fit p-value, scaled residuals, and AIC**

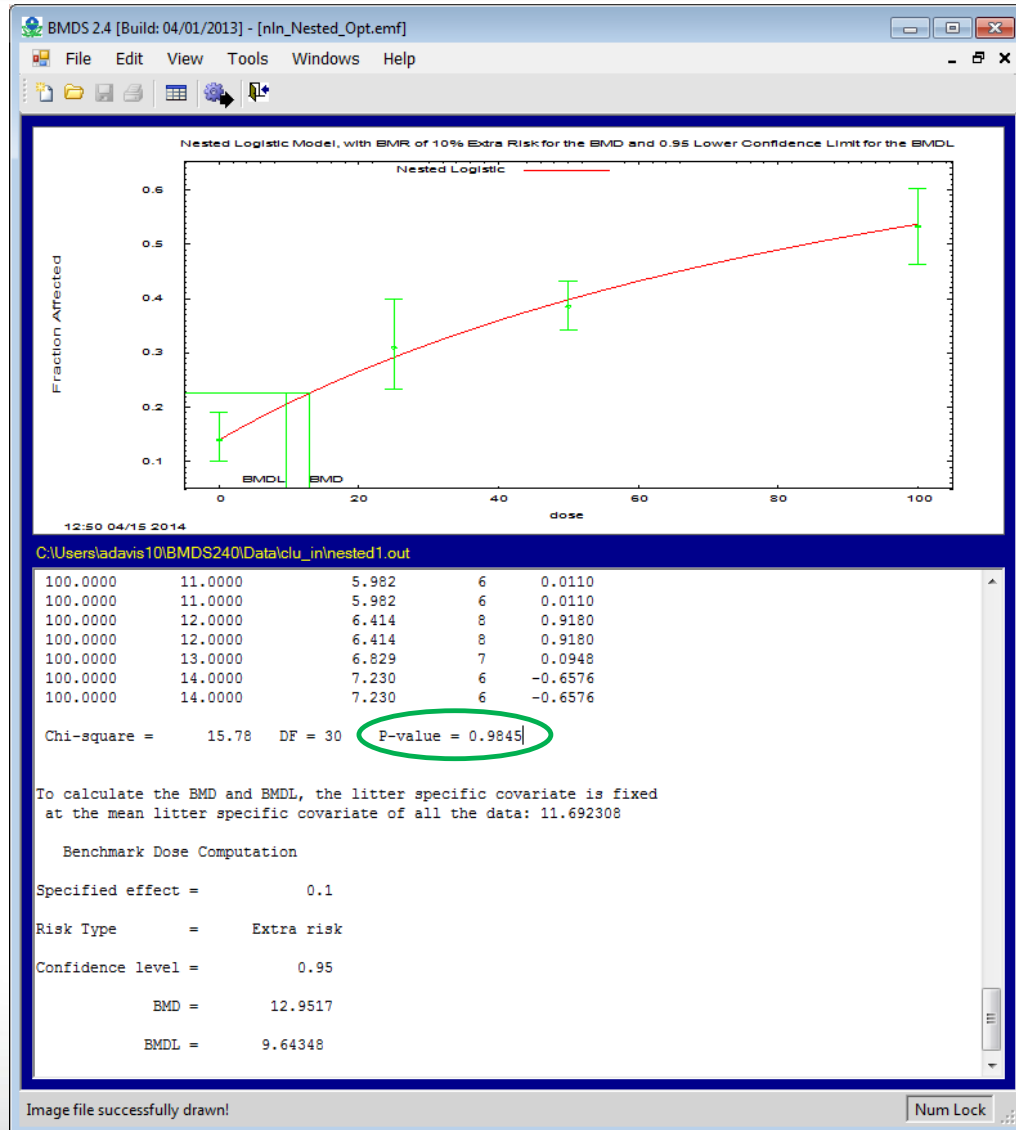

BMD Analysis – Six Steps

- **For dichotomous data:**
 - *Global measurement: goodness-of-fit p value ($p > 0.1$)*
 - Local measurement: Scaled residuals (absolute value < 2.0)
 - Visual inspection of model fitting

Global Goodness-of-Fit

- **Consider dropping high dose group(s) that negatively impact low dose fit**
- **Use PBPK models if available to calculate internal dose metrics that may facilitate better model fitting**
 - For highly supralinear curves, use of internal dose metrics may be helpful, especially in cases of metabolic saturation (e.g., dose-response shape will be linearized)
 - If one particular dose metric fits the response data more closely, this may be an indication that this dose metric is the metric of interest (i.e., C_{\max} vs. AUC)
- **Log-transform doses**
 - Consult a statistician to determine if log-transformation is appropriate, special care often needs to be taken with the control dose (i.e., $\log_{10}(0)$ is undefined)

PBPK Models and BMD Modeling

- **Care must be taken when performing BMD analyses with PBPK model-derived estimates of internal dose**
- **Most important question: Is the relationship between external and internal dose metrics linear across all doses?**
- **If yes, then it does not matter when BMD modeling occurs**
 - Can model external doses and then convert BMDs and BMDLs to internal doses (often advantageous if PBPK model is constantly updated or changed)
- **If no, then BMD analysis must be conducted using the internal dose metrics of interest**

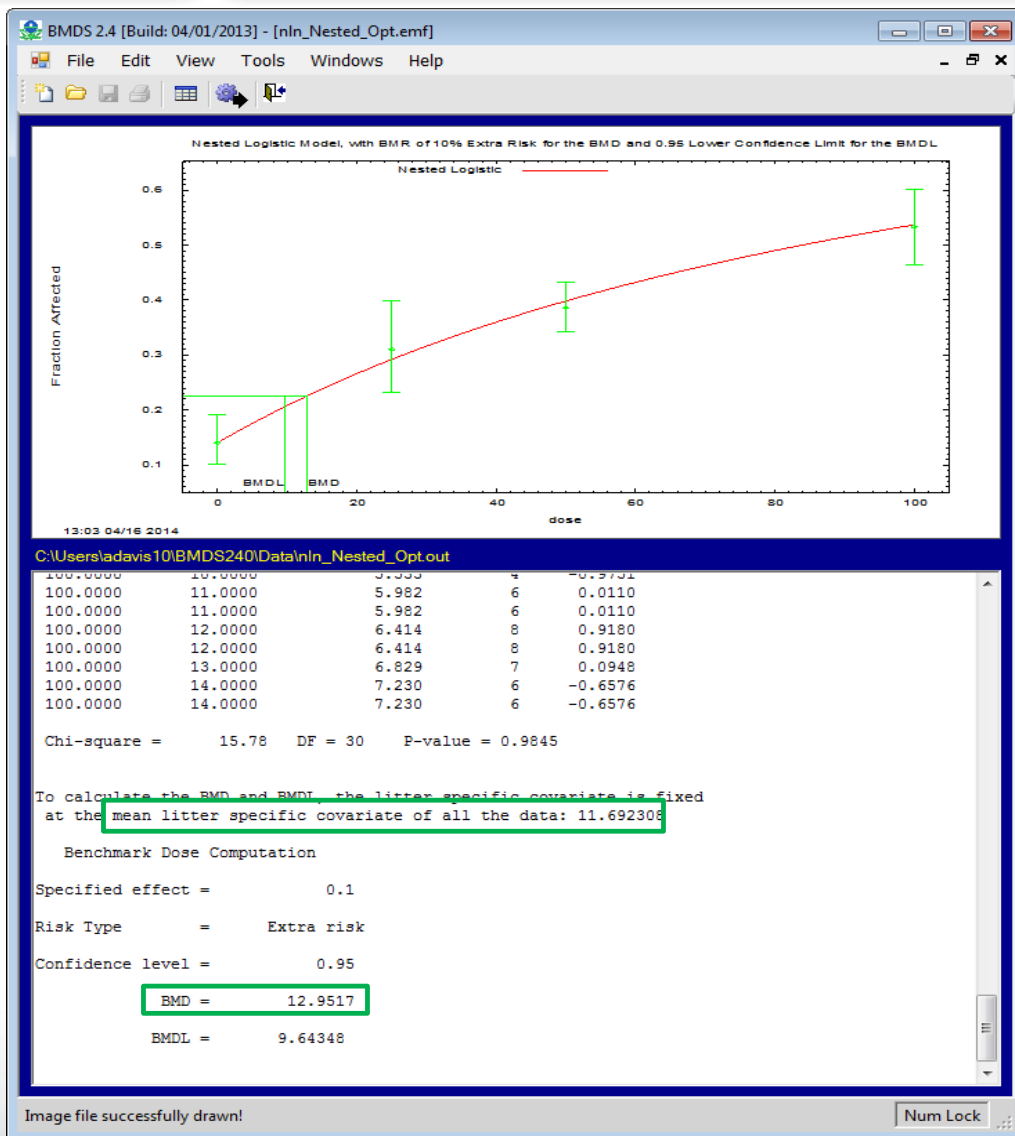

- **For nested dichotomous data:**
 - Global measurement: goodness-of-fit p value ($p > 0.1$)
 - *Local measurement: Scaled residuals (absolute value < 2.0)*
 - Visual inspection of model fitting

- **Global goodness-of-fit p-values are not enough to assess local fit**
 - Models with large p-values may consistently “miss the data” (e.g., always on one side of the dose-group means)
 - Models may “fit” the wrong (e.g. high-dose) region of the dose-response curve.
- **Scaled Residuals – measure of how closely the model fits the data at each point; 0 = exact fit**
 - Absolute values near the BMR should be lowest
 - Question scaled residuals with absolute value > 2

- The scaled residual of interest is estimated from the scaled residuals from the **Litter Data** for litters with a litter specific covariate value closest to the *mean litter specific covariate of all the data*
- **When multiple scaled residuals are obtained from samples with the same litter specific covariate, there are a number of options for assessing local fit**
 - **Maximum (absolute) scaled residual value**
 - Average (absolute) scaled residual value
 - Range of scaled residual values

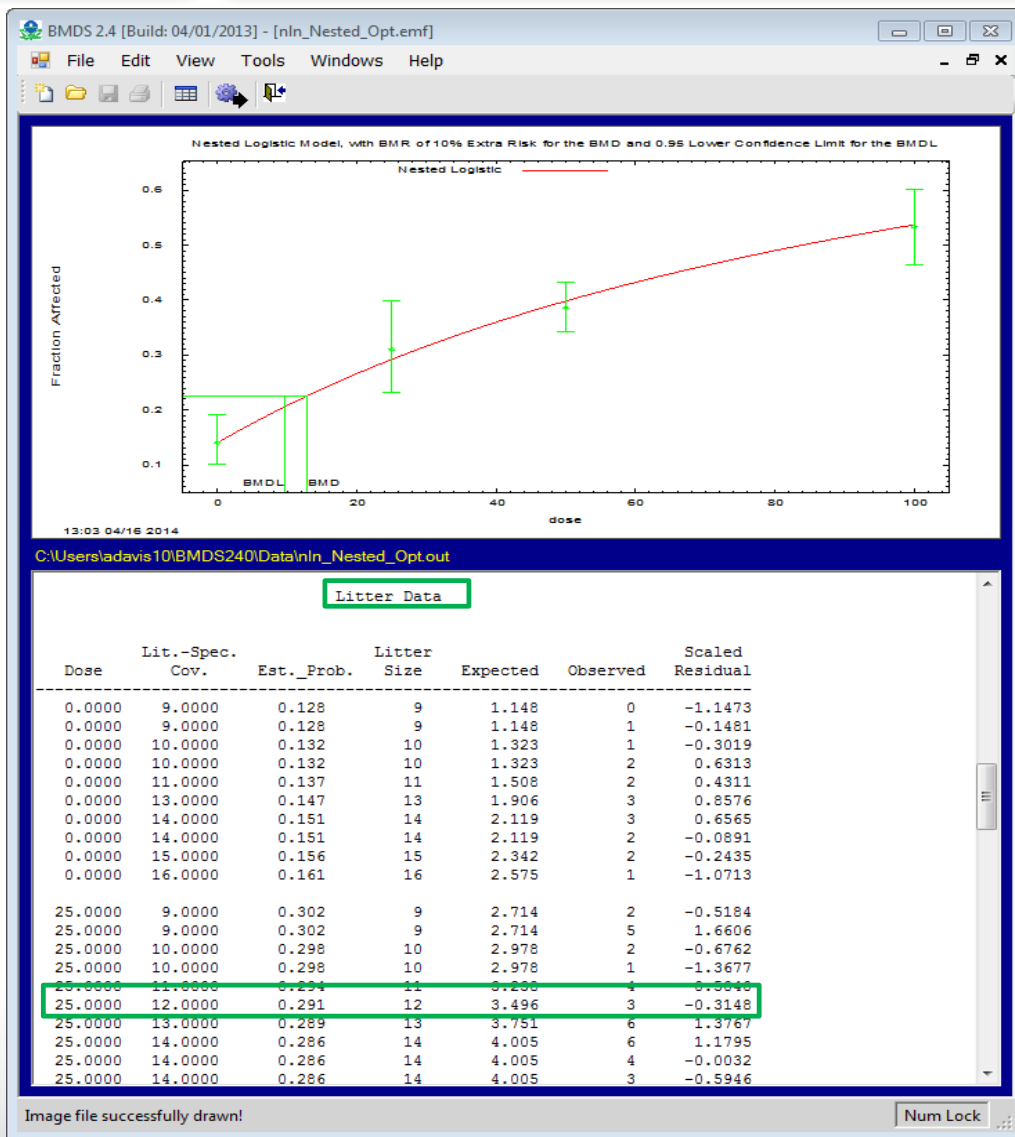

Scaled Residuals in Nested Dichotomous Models

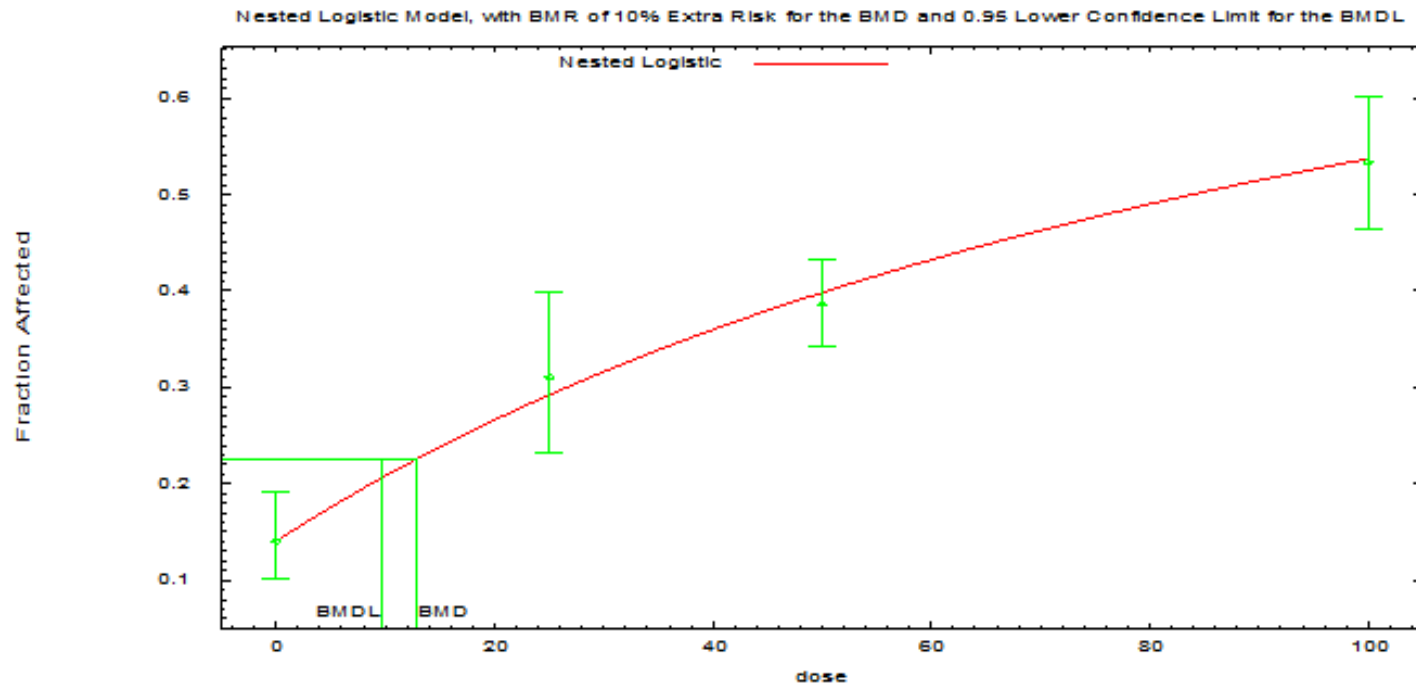

Scaled Residuals in Nested Dichotomous Models

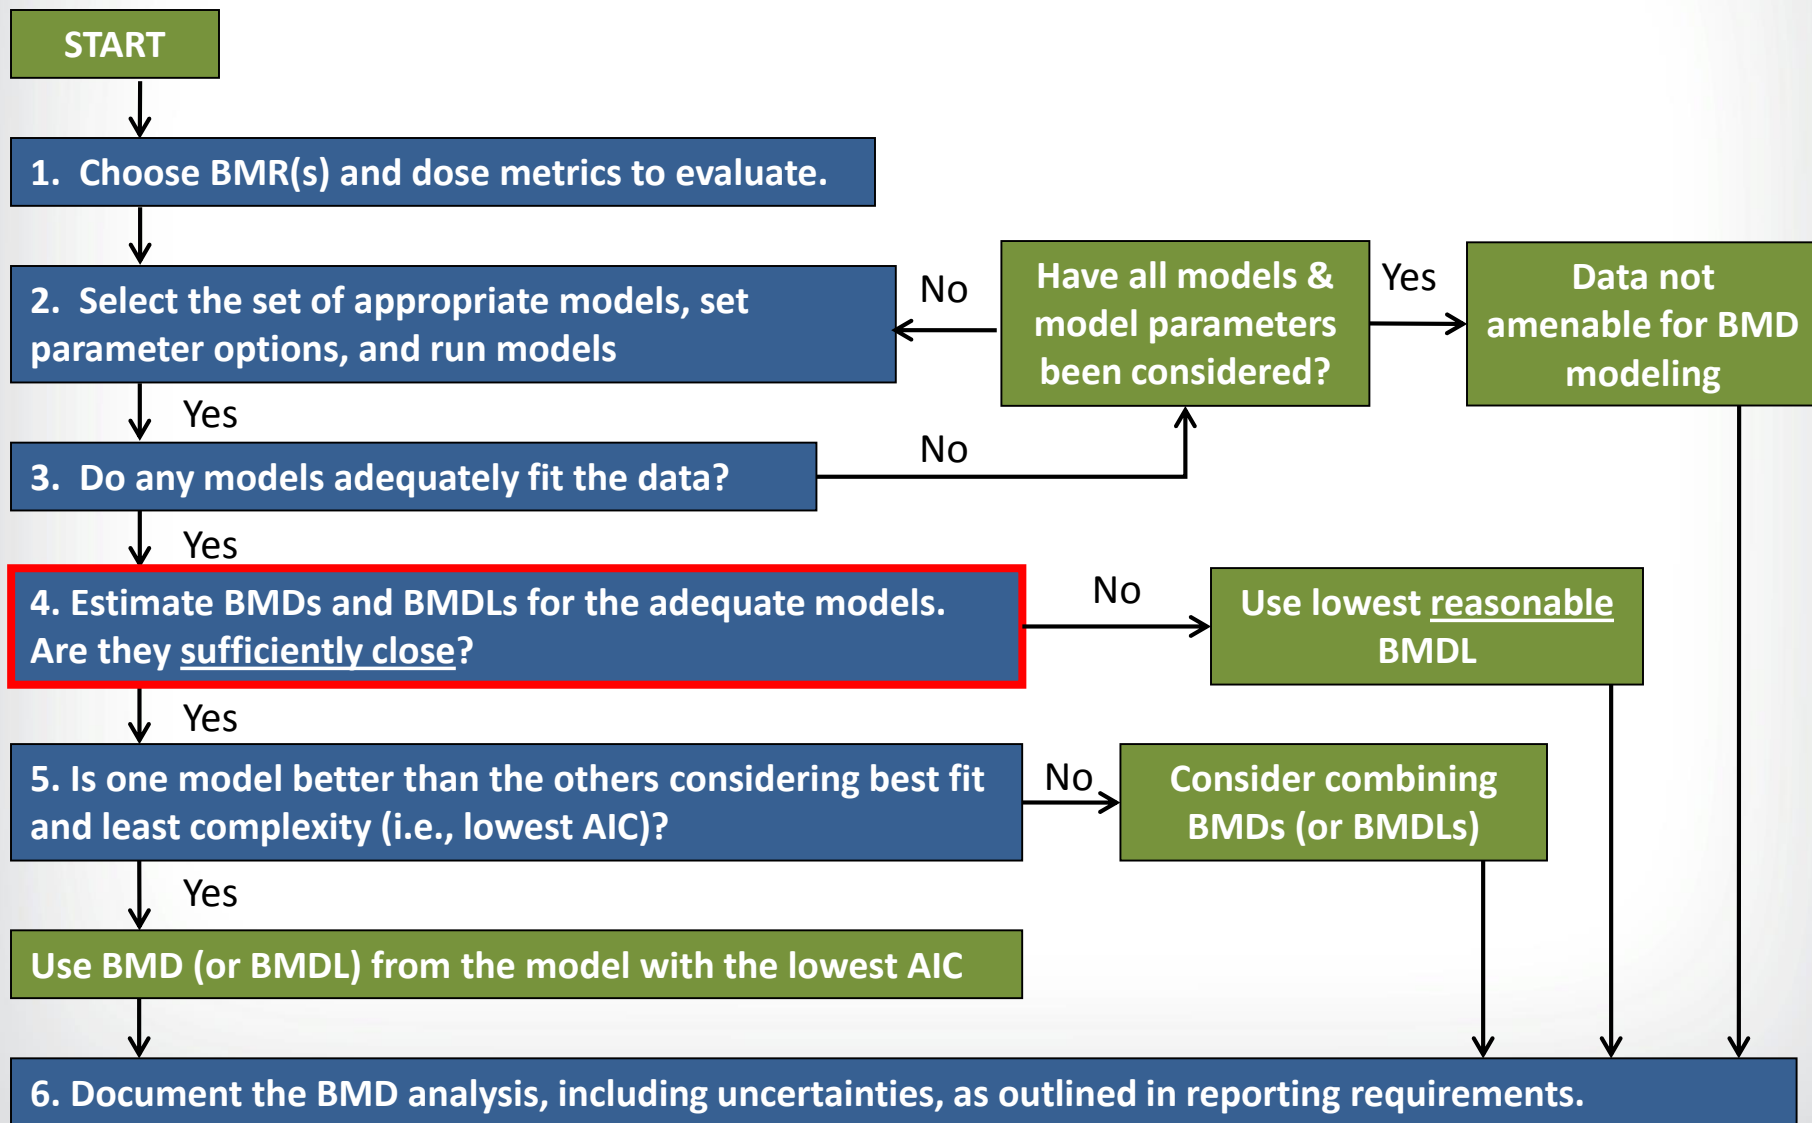

- **For nested dichotomous data:**
 - Global measurement: goodness-of-fit p value ($p > 0.1$)
 - Local measurement: Scaled residuals (absolute value < 2.0)
 - *Visual inspection of model fitting*

13:03 04/16 2014

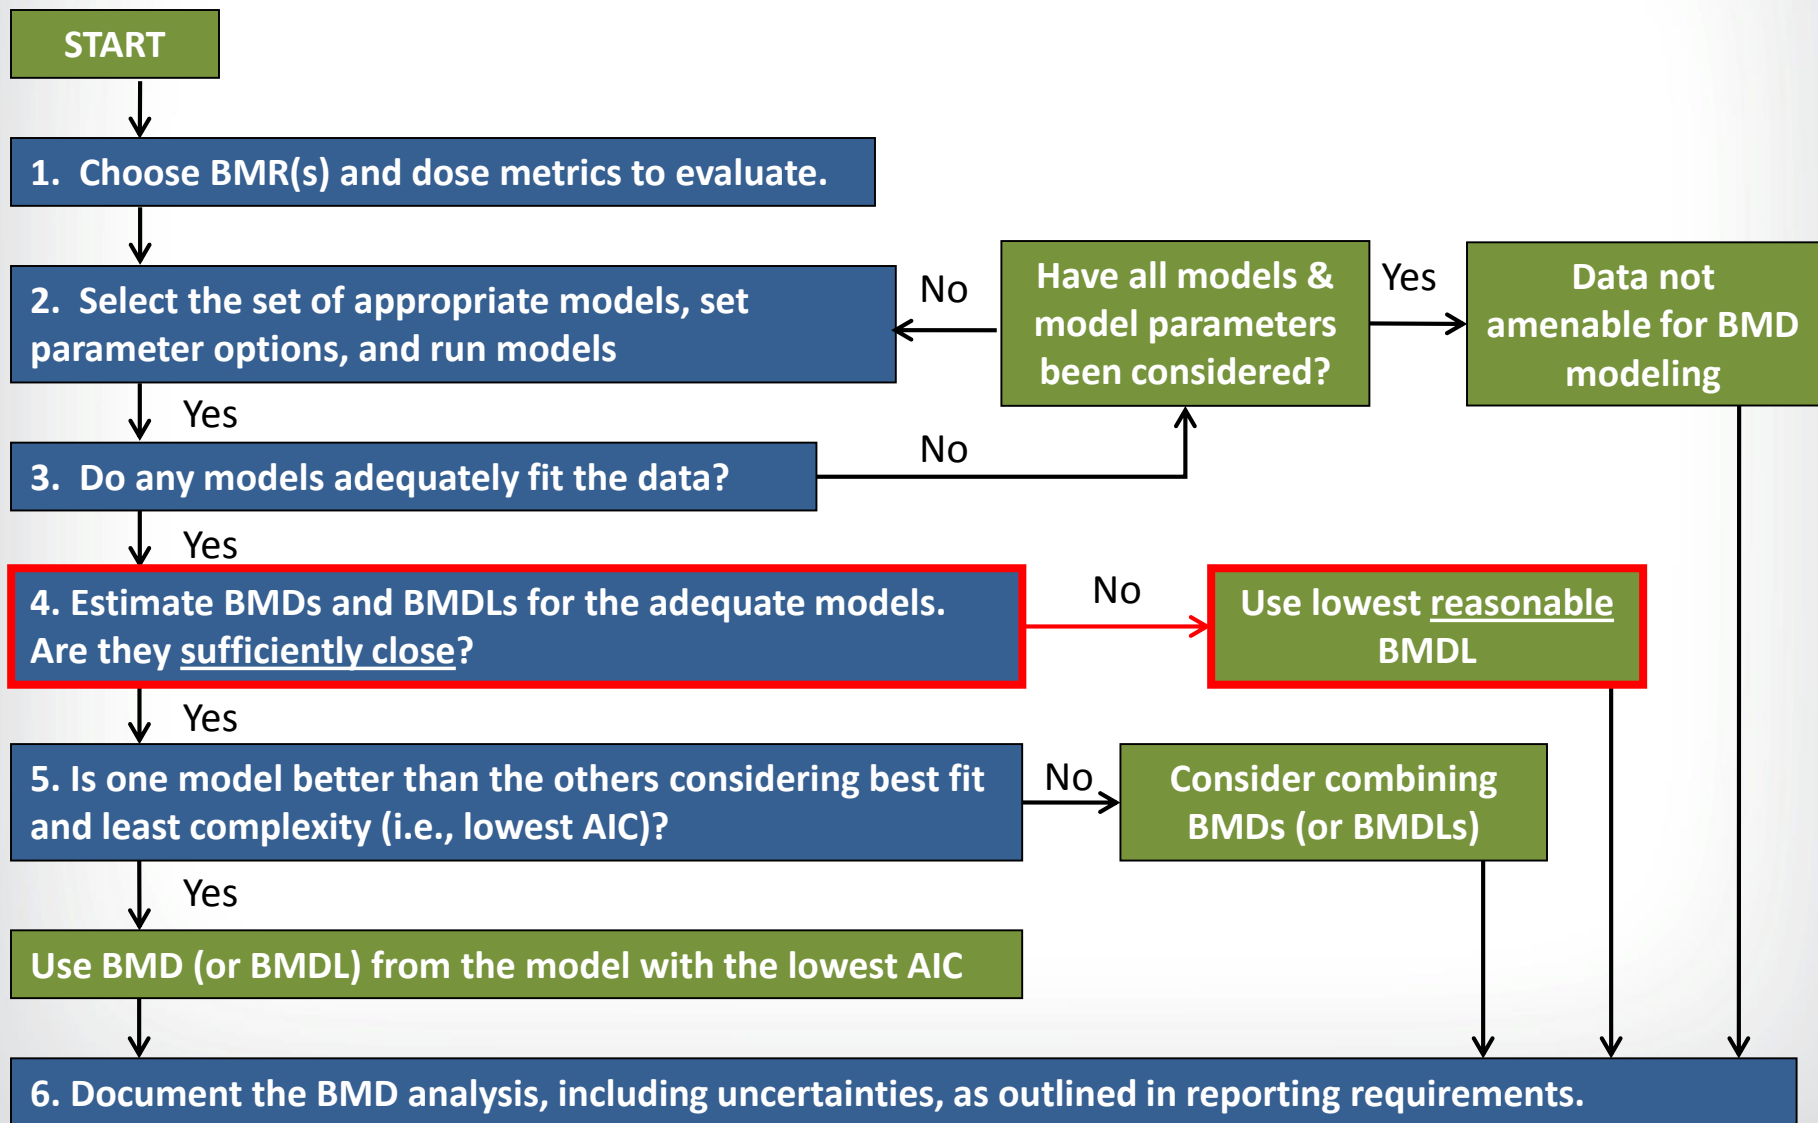

BMD Analysis – Six Steps

BMD Analysis – Six Steps

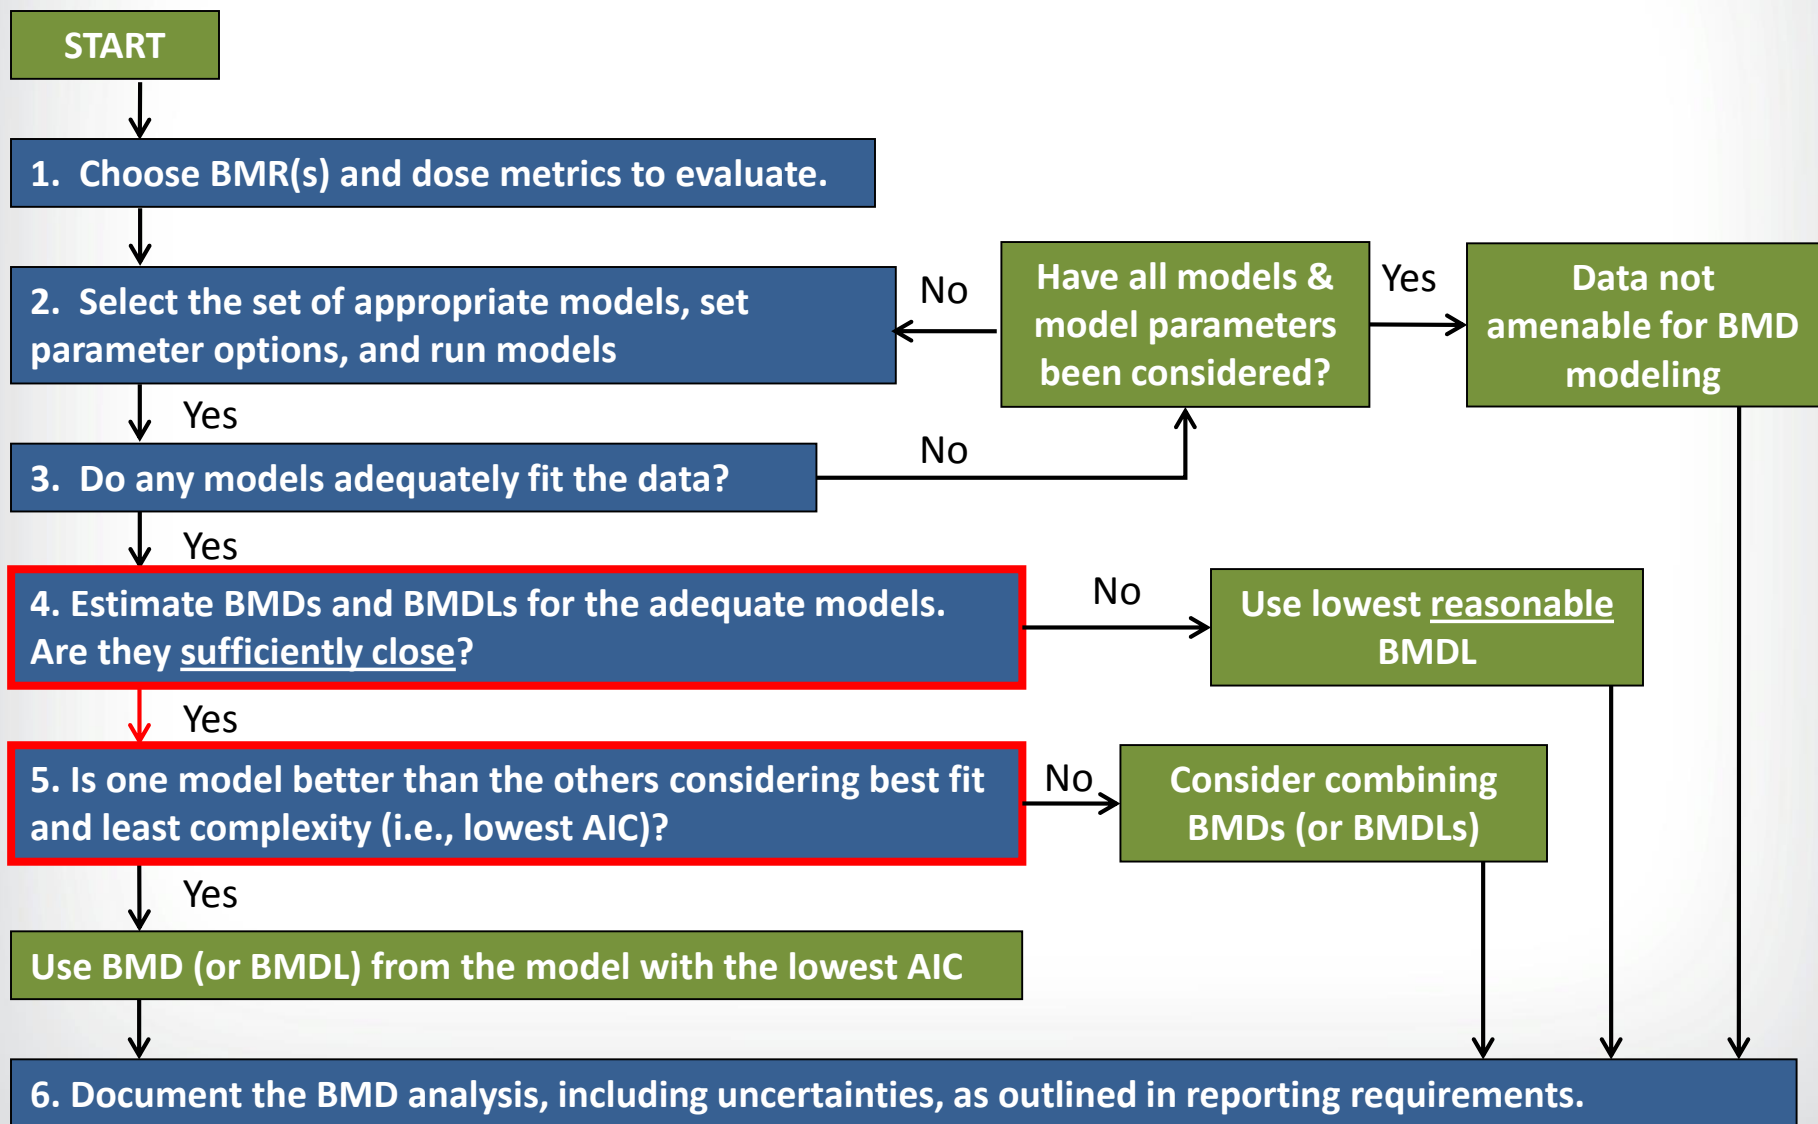

Are BMDL Estimates “Sufficiently Close”?

- **Often, more than one model or modeling options will result in an acceptable fit to the data.**
- **Consider using the lowest BMDL if BMDL estimates from acceptable models are not sufficiently close, indicating model dependence**
- **What is “sufficiently close” can vary based on the needs of the assessment, but generally should not be more than 3-fold.**

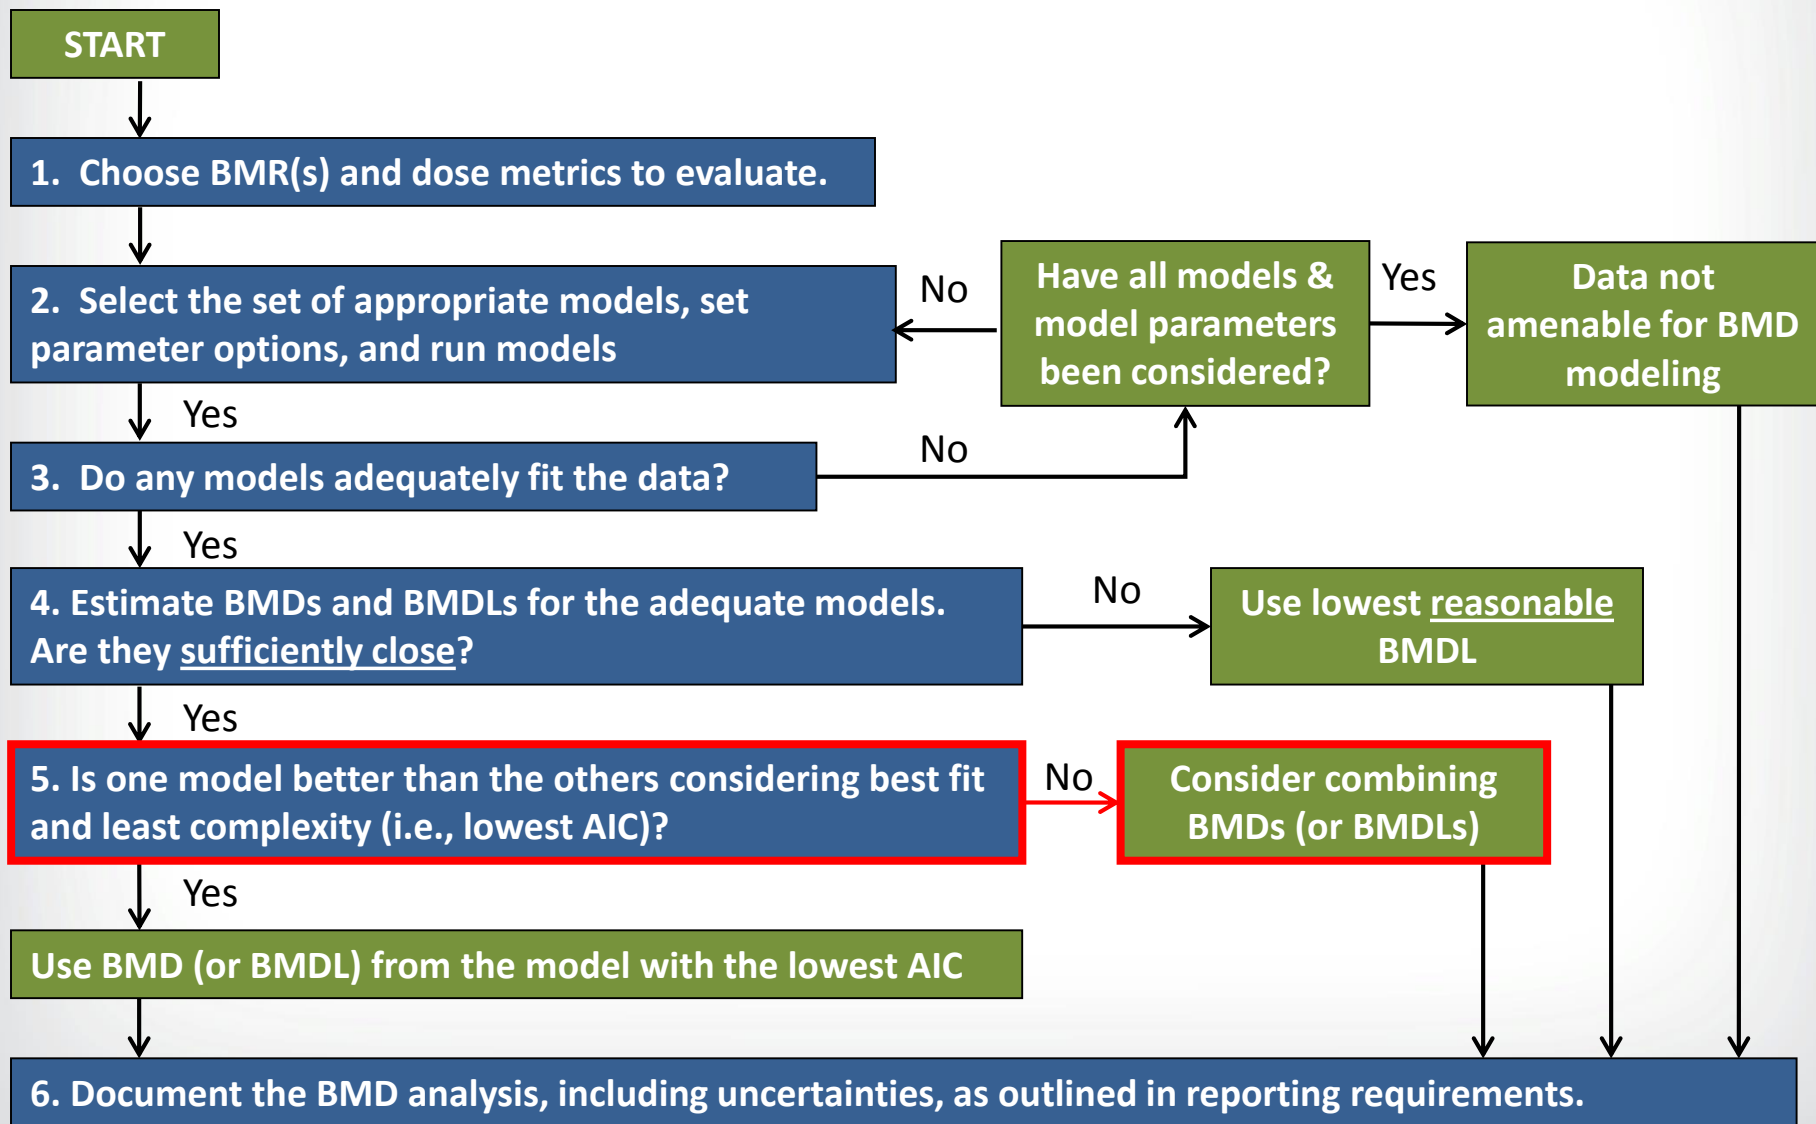

BMD Analysis – Six Steps

- **AIC = $-2 \times LL + 2 \times p$**
 - LL = log-likelihood at the maximum likelihood estimates for parameters
 - p = number of model degrees of freedom (dependent on total number of model parameters, number of model parameters that hit a bound, and the number of dose groups in your dataset)
- **Only the DIFFERENCE in AIC is important, not actual value**
- **As a matter of policy, any difference in AIC is considered important. This prevents “model shopping”**

	Litter Specific Covariate; Intralitter Correlation	No Litter Specific Covariate; Intralitter Correlation	Litter Specific Covariate; No Intralitter Correlation	No Litter Specific Covariate; No Intralitter Correlation
BMD ₀₅	505	658.131	526.799	
BMDL ₀₅	174.24	216.749	266.212	
AIC	1049.33	1053.46	1133.43	
p-value	0.2752	0.1601	0.00	
Grouped Scaled residual	1.3312	1.3538	2.0286	
θ_1 estimate	0.0331164	--	0.0340365	
θ_2 estimate	-0.410957	--	-0.431175	
Φ_1 estimate	0.200123	0.212445	--	
Φ_2 estimate	0.313042	0.312581	--	
Φ_3 estimate	0.213544	0.219964	--	
Φ_4 estimate	0.370267	0.371497	--	

- **Open the provided dataset titled “Nested_Exercise.dax”**
- **Run the Nested Logistic model against the data with the following parameterizations**
 - Litter Specific Covariate – Do Not Use
 - Intra-litter Correlation – Assume Zero
 - BMR = 5% Extra risk
- **Record the following data:**
 - BMD and BMDL
 - p-value, AIC, and Scaled Residual of Interest (1. find “mean litter specific covariate”; 2. look at grouped data and dose group closest to BMD; 3. find individual rows for which reported mean litter specific covariate is close to the value for all data; 4. average multiple values if necessary)
 - Parameter estimates for θ and Φ coefficients
