14. ABSTRACT

Contaminant mass flux/discharge can vary through time due to seasonal flow system dynamics, water supply well operations, and remediation activities. Therefore, technologies that provide repeatable, high-resolution mass flux/discharge datasets that can target the important zones within heterogeneous plumes efficiently are needed to optimize remediation performance and determine when to transition to less aggressive technologies and long-term monitoring. The objective of this project is to demonstrate the Vertebrae™ well system (VWS), a next-generation multiport horizontal well technology, for monitoring changes in per- and polyfluoroalkyl substances (PFAS) contaminant mass flux/discharge in groundwater through time.

Thank you for all your efforts and support!

# ABSTRACT

## INTRODUCTION AND OBJECTIVES

Contaminant mass flux/discharge can vary through time due to seasonal flow system dynamics, water supply well operations, and remediation activities. Therefore, technologies that provide repeatable, high-resolution mass flux/discharge datasets that can target the important zones within heterogeneous plumes efficiently are needed to optimize remediation performance and determine when to transition to less aggressive technologies and long-term monitoring. The objective of this project is to demonstrate the Vertebrae™ well system (VWS), a next-generation multiport horizontal well technology, for monitoring changes in per- and polyfluoroalkyl substances (PFAS) contaminant mass flux/discharge in groundwater through time.

## TECHNOLOGY DESCRIPTION

The VWS is a single, horizontal multiport system, with each port accessed via small-diameter tubes attached to screen segments or ports isolated with bentonite seals. The VWS technology can be applied as a variation of the conventional transect approach. Monitoring points are installed horizontally instead of vertically, with improved coverage along the width of the plume at targeted depths (i.e., horizontal horizons) with highest concentrations or flux, but with generally lower vertical resolution due to practical limits on placing multiple systems at different depths. The approach is advantageous because plumes are often anisotropic along horizontal bedding planes and the placement of multiple, closely spaced measuring points across a transect along a horizontal plane can be easily installed from a single boring, reducing costs. Furthermore, horizontal installations can allow access to zones that may be inaccessible via vertical boreholes.

## PERFORMANCE AND COST ASSESSMENT

Multiple VWSs were installed at the Grayling Army Airfield in Grayling, Michigan. Two VWSs (at different depth intervals) were installed transverse to groundwater flow (i.e., transects) downgradient of a PFAS source area. Following installation, performance monitoring was completed to assess various performance objectives. The demonstration confirmed the integrity of the grout seals separating screen sections, well screens can be placed accurately (+/- 1.5 vertical feet) within the subsurface (in comparable settings), single-well tracer techniques and fiber-optic-based distributed temperature sensing can be used to quantify groundwater flux, and the technology is appropriate for quantifying mass flux/discharge along transects. The main cost drivers of the technology are the number of VWSs and segments, VWS length and depth, and site lithology. As a simple example, two 500-foot-long VWSs (installed in comparable settings), both with up to 10 screens, can generally be installed in less than 1 week and drilling and materials may cost approximately $150,000. Costs for longer wells (800 to 1,200 feet) increase linearly, while the cost per foot increases for shorter wells (less than 300 feet).

## IMPLEMENTATION ISSUES

VWSs are most advantageous for difficult-to-access plumes under buildings, roads, flight lines, and other surface infrastructure, and therefore represent minimal potential to impact facility operations during installation and sampling. VWSs will be utilized primarily to facilitate long-term monitoring as opposed to plume delineation, because detailed lithologic information is not obtained during the directional drilling installation process. For optimal design and to maximize the performance of this technology, concentrations and the lithology of the plume should be well-understood to support VWS design.

# EXECUTIVE SUMMARY

## INTRODUCTION

Contaminant mass flux/discharge estimation is challenging because it requires high-resolution measurements of both contaminant concentrations and groundwater flux, which can be highly variable spatially due to orders of magnitude variations in concentration and hydraulic conductivity in short distances. Mass flux can also vary through time due to seasonal flow system dynamics, water supply well operations, and remediation activities. Therefore, technologies that provide repeatable, high-resolution mass flux/discharge datasets that can target the important zones within heterogeneous plumes efficiently are needed to optimize remediation performance and determine when to transition to less aggressive technologies and long-term monitoring.

Of the methods that are available to measure contaminant mass flux/discharge, the transect method is probably the most insightful and commonly used because it couples with characterization (Guilbeault et al. 2005; Einarson et al. 2010; Interstate Technology & Regulatory Council [ITRC] 2010; Einarson 2017). Traditionally, the transect approach involves vertically drilled permanent or temporary (i.e., snapshot) borings, well clusters, or multiport systems oriented perpendicular to groundwater flow across a groundwater plume. However, this approach can be costly because it requires many individual vertical boring locations (which requires surface access) given typical high spatial variability in plumes, and many hundreds of feet of drilling with uncertainty in the horizontal direction between vertical locations. This is especially important if the target interval is relatively deep or requires high vertical resolution monitoring or sampling at each location along the transect. Direct contaminant flux approaches such as passive flux meters (Annable et al. 2005; Klammler et al. 2007) are also generally applied at high spatial resolution along monitoring transects, typically using vertical deployments and conventional wells rather than multiport systems.

The conventional transect method for characterizing contaminant mass flux relies on a series of temporary or permanent vertical monitoring points providing data in vertical profiles along a transect across the entire plume, perpendicular to groundwater flow (ITRC 2010). The monitoring points are sampled to provide concentration data across the control plane at appropriate lateral and vertical spacing to capture the plume concentration distribution (boundaries and internal variability). An appropriate method for measuring groundwater flux at similar high resolution is also required and the combined groundwater concentration and flux data are used to assess contaminant mass flux/discharge across the transect (note: this is focused on the mobile groundwater phase and water phase, and does not capture mass stored as sorbed phase within the plume, which can be significant in many lithologies and relevant to site management decisions). The purpose and scope of this project is to demonstrate the Vertebrae™ well system (VWS), a next-generation segmented, nested horizontal well technology (Koenigsberg et al. 2018), for monitoring changes in contaminant mass flux/discharge emanating from source zones and high-concentration areas through time (Figure ES-1, below). During the past decade, more than 200 VWSs have been installed in the field for general plume monitoring, remediation fluid injections, air sparging, and soil vapor extraction; however, they have not been specifically designed to monitor mass flux/discharge and have not previously been used for per- and polyfluoroalkyl substances (PFAS) contaminants.

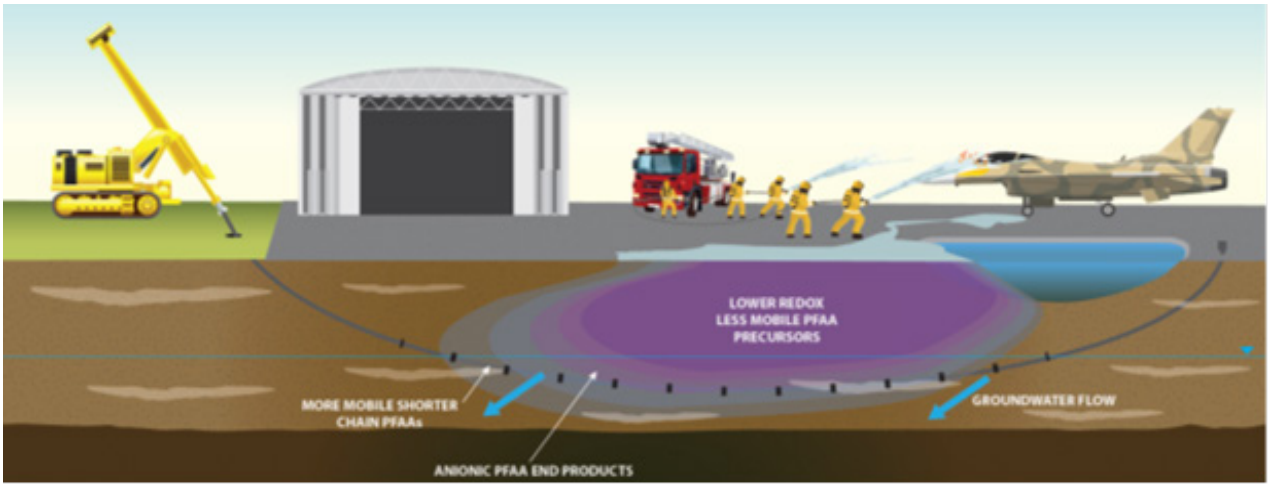

**Figure ES-1. Conceptual Depiction of a Vertebrae™ Well System Measuring PFAS Mass Flux/Discharge**

Further development of the application of the VWS technology will benefit the U.S. Department of Defense (DoD) and the environmental community at large because it will contribute to advancement with both cost and effectiveness in understanding contaminant mass flux/discharge in site assessment, remediation, and monitoring. In particular, the VWS will enable precise and repeatable monitoring of mass concentrations and discharge with intervals oriented to intersect zones with high concentrations/ flux emanating from complex source zones through time, supporting more reliable risk assessment, remedy performance assessment and optimization, and transition from active to passive remedies. The technology is applicable to many types of groundwater contamination; however, it offers particular potential for monitoring mass discharge changes through time from PFAS sources. Scaled up across the portfolio of DoD sites, this could result in significant total savings for remedy implementation through more reliable characterization, risk assessment, flux-based decision making, and better remedy design and operation with improved performance monitoring.

## OBJECTIVES

The overall goal of this project is to demonstrate and validate the Vertebrae™ horizontal multiport well system as a technology for reliable long-term monitoring of contaminant mass flux/discharge from PFAS source zones. Specific performance objectives are presented in Table ES-1, below.

**Table ES-1. Performance Objectives**

| Performance Objective | Data Requirements | Success Criteria | Success Criteria Achieved? |
|---|---|---|---|
| **Quantitative Objectives** | | | |
| 1. Accurate and reliable placement of screens in subsurface. | Bore-path drilling navigation data, and post-installation geophysical survey data. | Eighty percent (%) of all drilling navigation data agree within 1.5 foot (elevation) of the bore path elevation and 80% of the as-built data agree within 1.5 foot of the planned target depth elevations. | **Yes**<br>Six of six screens along horizontal section were within 1.5 vertical feet of the target elevations and positions. |

**Table ES-1. Performance Objectives (Continued)**

| Performance Objective | Data Requirements | Success Criteria | Success Criteria Achieved? |
|---|---|---|---|
| 2. Validate methods for groundwater flux measurement with VWSs. | Hydraulic conductivity, hydraulic gradient, tracer test data, active fiber optic distributed temperature sensing (A-DTS) data. | Complete successful field testing of methods. For each method estimates that are repeatable (±25%) and agree with the averages from all the methods within 25% according to an analysis of variance statistical test (within 25% at an 80% confidence). | **Yes** Both the A-DTS and single-well tracer test methods are considered to have achieved success for this performance objective, based on modified criteria. |
| 3. Assess comparability of samples collected from VWS screens to grab samples. | Concentration data from Vertebrae™ screens and co-located vertical cores/wells or groundwater grab samples. | Perfluorooctanoic acid (PFOA) and perfluorooctane sulfonate (PFOS) concentrations measured from the Vertebrae™ screens agree within 1 order of magnitude for at least 75% of co-located grab samples. | **Yes** Sample results from the VWS are consistent with conventional sampling methods. |
| 4. Demonstrate method to identify appropriate mass flux zones to target Vertebrae™ placement. | All currently existing hydraulic, hydraulic profile tool, and groundwater grab sample concentration data as well as additional high-resolution data developed during the pre-design investigation. | Achieved if a relationship between pre-design data availability and the predicted mass discharge measured from the resulting VWS designs can be developed, and if this relationship indicates the VWS design will yield a mass discharge estimate within ±25% of the estimated derived from other data. | **Partially** A clear relationship between data used and the calculated mass discharge was developed via a practical method. However, the analysis did not yield results that agreed within ±25% |
| 5. Validate VWS application for quantifying mass flux/discharge along transects. | Mass flux/discharge estimates normal to groundwater flow for VWSs and conventional vertical borings/ wells installed along a nearby transect. These estimates will be derived from PFAS concentration data and darcy flux values determined from hydraulic testing, tracer testing, the A-DTS. | Mass flux/discharge estimates with VWSs agree with conventional approaches within 25% with equal or lower uncertainty estimated through propagation of uncertainty statistical techniques. | **Yes** None of the methods meet this statistical level, however, this may have been an unrealistic success criterion. The average results for both the HPT and DTS agree with the EVS result within an order of magnitude and event-to-event variability is similar for all of the methods. This implies that the differences in methods are related more toward a systemic consistent bias rather than precision and repeatability. Consequently, the results support the use of VWS for PFAS mass discharge estimation. |

**Table ES-1. Performance Objectives (Continued)**

| Performance Objective | Data Requirements | Success Criteria | Success Criteria Achieved? |
|---|---|---|---|
| 6. Verify materials' compatibility with PFAS. | Rinsate blank and PFAS stock solution samples after contact with VWS components. | PFOS and PFOA are less than the United States Environmental Protection Agency (USEPA) Maximum Contaminant Levels (MCLs) of 4.0 nanograms per liter in rinsate blank samples and PFAS loss from the sample due to sorption to well materials is less than 10% or the analytical precision (whichever is greater) for each tested compound. | **Yes** The VWSs can be tested prior to production for certification to be free of primary PFAS analytes. |
| **Qualitative Objectives** | | | |
| 1. VWS can assess contaminants and conditions along the flow path in a longsect configuration. | Contaminant concentrations data from longsect VWS, monitoring wells, and vertical aquifer profile samples. | PFAS concentration data collected from different screen intervals located progressively downgradient follow discernable and consistent trends, indicating the samples represent locations along a constant flow path. | **Yes** Samples from the VWS were generally consistent with other sample types and exhibited high spatial correlation. |
| 2. Demonstrate integrity of grout seals to isolate individual screen segments. | Pressure data from injection tests and A-DTS temperature data measured under passive and active (heated) conditions. | Pressure data do not show clear evidence of seal failure and A-DTS data delineate continuous seals that are at least 5 feet long between each well screen. | **Yes** Grout seals in the horizontal section are placed where intended and are largely functioning as intended (hydraulic separation). |
| 3. Identify challenges and limitations of VWSs. | Feedback from drillers, installation, and monitoring personnel and project technical staff. | Challenges and limitations are understood and can be readily mitigated. | **Yes** No implementation or operational challenges were identified that would limit widespread application. |
| 4. Assess robustness of the technology. | Feedback from geologists and field staff regarding observed ruggedness and performance of screens, sampling ports, connections, and other well components. | No fundamental design flaws/limitations identified, and no systemic problems experienced during installation and sampling. | **Yes.** |

## TECHNOLOGY DESCRIPTION

The VWS is a single, small-diameter horizontal well that contains multiple isolated screen segments as individual ports each with a small-diameter tube connected to ground surface. Essentially it is an engineered multiport well that is installed horizontally instead of vertically (Figure ES-2, below). The VWS can provide another transect method option as a complement or alternative to the conventional vertical installation transect option. The VWS is unique, with many discrete screen zones running horizontally along its length and separate, small-diameter tubing

plumbed from each screen to the surface. Grout, which is tremied in, is used to isolate the individual tailor-designed screen intervals. The VWS technology can be applied as a variation of the conventional transect approach. The difference is the monitoring points are installed horizontally instead of vertically, with improved coverage along the width of the plume at targeted depths with highest concentrations or flux, but with generally lower vertical resolution due to practical limits on placing multiple systems at different depths. The VWS approach is novel and advantageous because multiple closely spaced measuring points across a transect can be easily installed from a single boring (reducing costs) and contaminant zones that may have been previously inaccessible via vertical boreholes can be characterized. Currently, detailed geologic information is not readily available during the drilling process; therefore, an accurate understanding of contaminant distribution within the site hydrostratigraphy from high-resolution characterization using direct-push methods or vertical borings to obtain profiles is required to optimize placement of the horizontal wells and to select target intervals for the monitoring zones.

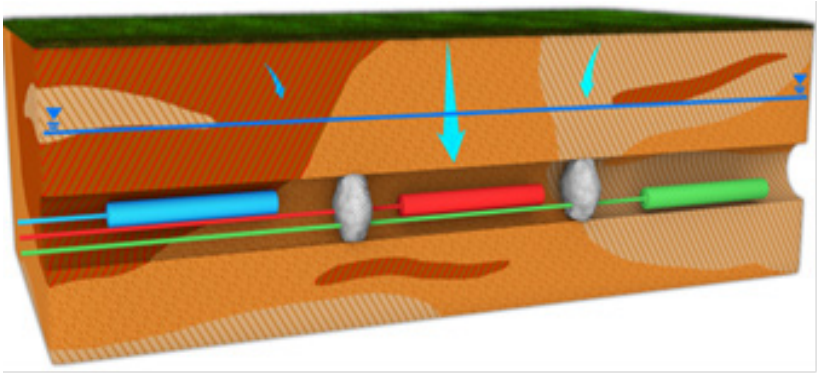

**Figure ES-2. Vertebrae™ Well System (VWS)**

*The VWS contains multiple screen segments separated by grout seals with independent connections to the surface. It can be thought of as a nested well installed horizontally.*

VWSs are installed using horizontal directional drilling (HDD), which is a mud rotary drilling process that uses a specialized rig and asymmetric bit to drill a curved borehole along a predetermined bore path and the prefabricated VWS is pulled into the borehole (Figure ES-3, below). The VWS is a multiport horizontal well that has been installed with as many as 18 discrete screened zones (however, these values are not upper limits; additional screened zones are feasible). To date, VWS wells exceeding 900 feet long and 45 feet deep have been installed, but longer and deeper wells with currently available drilling technology are feasible. The VWS can be thought of as a nested well with small-diameter tubes installed horizontally instead of vertically. Individual screen lengths range from 3 to 30 feet with separate 0.5- to 1.5-inch-diameter tubing plumbed from each screen to the surface. Multiposition monitoring along horizontal paths can be more efficient because it is aligned with hydrologically significant zones within and at the boundaries of aquifers parallel to layering typical of sedimentary facies. Grout is used to isolate the individual screen intervals within the horizontal well (shown on Figure ES-2, above) and reliable placement is key to effective installations tested herein. EN Rx, Inc. has developed a proprietary grout seal mixture to increase elasticity, longevity, and sealing efficiency to isolate the intervals in each horizontal boring. The VWS is compatible with all common contaminant types and has been used at sites with PFAS (this project was the first site where the VWS was deployed for monitoring PFAS), petroleum hydrocarbons, chlorinated solvents, metals, and high salinity.

**Figure ES-3. Photographs of the Installation of the VWS**

## PERFORMANCE ASSESSMENT

The data collected as part of this project were evaluated to determine if the success criteria for specific quantitative and qualitative performance objectives presented in Table ES-1, above, were achieved. This section discusses the assessment of each performance objective.

### *Quantitative Performance Objective 1: Accurate and Reliable Placement of Screens in Subsurface*

This performance objective is intended to:

- Assess the reliability of bore-path navigation data for documenting as-built completion.
- Verify that the VWS can be successfully installed at planned target depth intervals.

The following data were collected to evaluate accurate and reliable placement of the VWS screens:

- A walkover locating system was used to track the position of the drill head. The position of the drill head was marked when an additional drill rod was added to the drill string (every 10 feet).
- The locations of the screens at the shallow and deep transects were determined using RF inductive line tracing with a multifrequency transmitter and receiver.

The coordinates were then used to calculate vertical differences for comparison to the success criteria. The goal was to install the VWS within 1 foot of the planned target depth. However, there are inherent limitations in the accuracy of depth measurements collected during and after directional drilling. For these reasons, depth measurements during (drilling navigation data) and after VWS installation (geophysical methods) have an inherent irreducible uncertainty of +/- 0.5 foot. Therefore, the depth accuracy of +/- 0.5 foot was added to the goal of +/- 1 foot, resulting in the overall target tolerance limit of 1.5 feet.

The differences between the measurements were within the tolerance limit of +/- 1.5 feet for all six horizontal screens. When evaluating this performance objective, only the six shallow transect VWS screens along the horizontal section were considered (Figure 32). The two screens on the slopes (one at each end) of the shallow transect were omitted due to decreased accuracy of the walkover locating system when drilling at an angle from horizontal. When drilling at an angle, the three signals (front, back, and center sight) emitted by the sonde travel a longer distance to the receiver at the surface, which decreases the accuracy. A future recommendation (see Section 9) is to avoid placing screens on the sloped portion of the wellbore, due to decreased locating accuracy. In addition, the angled screen orientation increases the potential for grout intrusion into the screen, which is another reason to avoid installing screens at an angle. *Based on the discussion above, the performance objective related to accurate and reliable placement of VWS screens in the subsurface is considered achieved.*

***Quantitative Performance Objective 2: Validate Methods for Groundwater Flux Measurement with VWSs***

This performance objective is intended to assess the reliability and usefulness of several different methods for measuring groundwater flux across a VWS. Groundwater flux across the transect was measured by multiple independent methods. The first method used K estimated from hydraulic tests completed during hydraulic profile tool (HPT) in the VWS well screens and the measured site hydraulic gradient according to Darcy's Law. The second method was based on groundwater flux directly measured from single-well tracer tests (SWTTs). The third method used data from active fiber optic distributed temperature sensing (A-DTS). Because the DTS system was only installed along the shallow transect, the groundwater flux and flow calculations for each method are compared for only the shallow zone.

Figure ES-4 (left), shows the average screen segment flows (average of eight monitoring events) for each of the primary comparison methods (HPT, SWTT, and A-DTS). Figure ES-4 (right) shows total transact calculated flow for each monitoring event. For comparison, this figure also shows average flows calculated using K-estimates based on size analyses from soil core samples ("Grain Size") and geostatistical-based (i.e., kriging) model of K-distribution based on all available K information at the site. The results based HPT data are notably lower than the other two methods for all segments and events. It is likely that for the Grayling Army Airfield (GAAF), this is a biased-low method because the range for most K measurements at the GAAF (Figure 34, 30 to 300 ft/day) is near the approximate upper method limit for HPT testing (approximately 50 to 100 ft/day). Therefore, the HPT method is not considered reliable for the GAAF; however, it may be appropriate for sites with lower hydraulic conductivity.

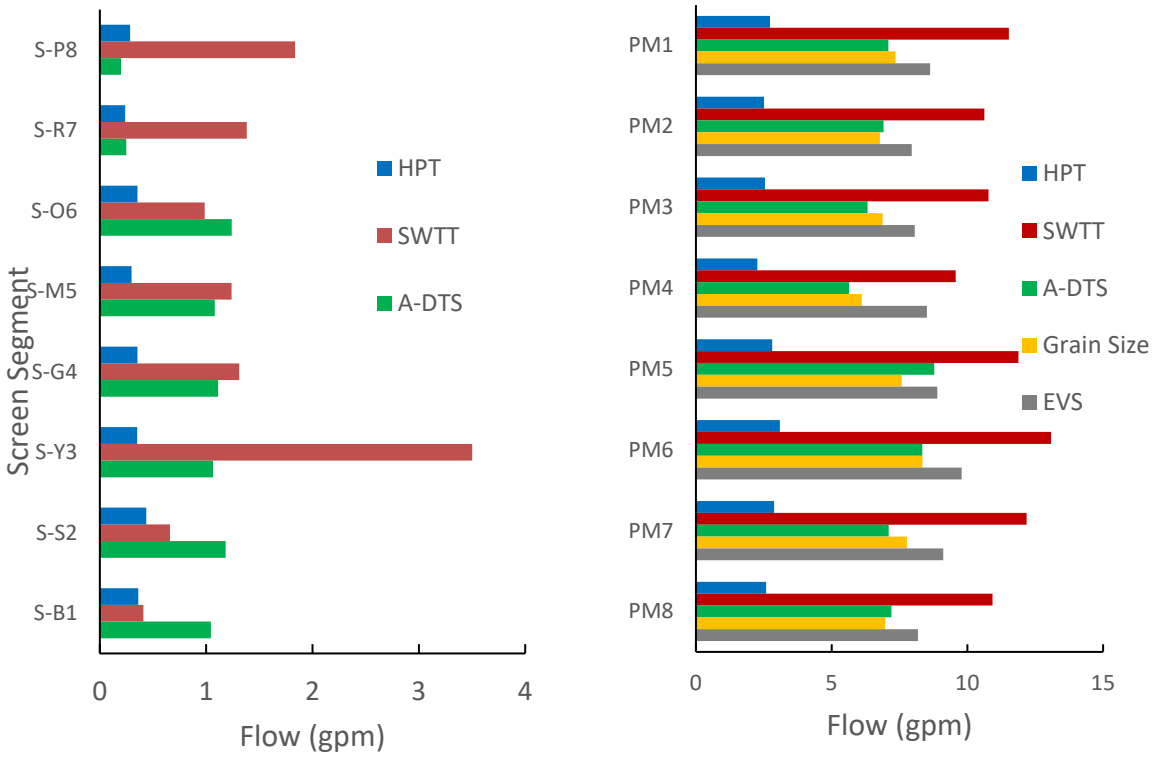

**Figure ES-4. Average Screen Segment Flows (left) for HPT, SWTT, and A-DTS, and Total Transact Calculated Flow for Each Performance Monitoring Event (PM1, PM2, etc.) for All Methods (right).**

The results for the DTS and SWT methods are similar for some screen segments and monitoring events, however, there are some screen segments where the SWTT method is up to twice as high as the DTS method. Based on the highly uniform K distribution at the site (Figure 34), it is unlikely that much higher permeability zones exist at those screens, and rather the SWTT method may be less reliable or biased high at these locations. In the Demonstration Plan (Divine et al. 2021c), it was proposed that success would be evaluated individually for each of the three methods and the performance objective would be considered to be achieved if:

- Repeated flux estimates for a specific method have an average relative percent difference (RPD) of <±25%.
- If through application of statistical analysis of variance, the result for a specific method agrees within 25% at an 80% confidence with the average of all methods.

If one method is determined to have failed, its result will be excluded from the average. For the relative standard deviation (RSD) for total transect flow across all eight monitoring events is similar, 14 and 10% for the DTS and SWTT methods, respectively. Because the HPT data are considered biased low, this second component of the success criteria cannot be evaluated as stated. Generally, it is believed that some SWTT results for individual screens may be biased high because the low geologic heterogeneity would be expected to result in more uniform values across screen sections; however, conclusive data are not available requiring that the SWTT results be considered less reliable than the HPT results. Therefore, both methods are considered reliable and application of an averaging and complimentary approach likely results in the best estimate for the GAAF.

*Based on modified criteria, both the DTS and SWTT methods are considered to have achieved success for this performance objective.*

***Quantitative Performance Objective 3: Assess Comparability of Samples Collected from VWS Screens to Grab Samples and Conventional Monitoring Wells***

This performance objective is intended to demonstrate that the groundwater samples collected from VWS screens are comparable to groundwater samples collected by conventional sampling methods commonly used in site characterization investigations, such as grab (e.g., VAP) samples obtained from direct-push drilling systems and samples from vertical monitoring wells. This performance objective was defined to confirm the overall representativeness of samples collected from the VWS and still accommodate irresolvable variances that may be the result of plume spatial variability caused by small-scale aquifer heterogeneity and flow system, and source variability and inherent differences in sampling methods.

Samples were collected quarterly from each individual screen in each VWS. These results were compared to nearby co-located groundwater samples from vertical borings and multilevel or conventional monitoring wells. These included one-time VAP grab samples collected as part of the prior ESTCP project at the GAAF (ER19-5203) and this ESTCP project. New multilevel and conventional wells installed during this project were also sampled multiple times. Sampling of these wells coincided sampling of the VWSs.

The high-resolution groundwater data generated from the previous ESTCP project at the site (completed in 2019) were evaluated to provide a basis for the success criteria for this performance objective. Numerous borings were installed previously, and VAP groundwater samples were collected from six to eight discrete intervals for each boring, generally between 15 and 50 feet below ground surface. Because the interval between 20 to 30 feet is the most important, the RSD of all samples collected from this interval was calculated for each boring. In general, RSD values range from less than 10% to more than 100% and appear to be independent of concentration magnitude. The average RSDs for PFOA and PFOS are 77 and 73%, respectively. Considering the uncertainty and limitations of the data, the average RPD for these data for the target interval is estimated to be 80%. In general, sample results from the VWS are consistent with conventional sampling methods. The average RSDs for PFOA and PFOS are 59 and 62% (less than the goal of 80%), range from 1 to 182%, and appear to be independent of concentration magnitude. *This comparison confirms the overall representativeness of samples collected from VWSs and the criteria for this performance objective are considered achieved.*

***Quantitative Performance Objective 4: Demonstrate Method to Identify Appropriate Mass Flux Zones to Target VWS Screen Placement***

This performance objective is intended to assess the practical and cost-effective use of prior site information and pre-design vertical characterization data to design a VWS that is optimally placed and will yield reliable contaminant mass flux/discharge information. Data used to support the assessment of this performance objective included all previously existing HPT and VAP groundwater grab sample concentration data as well as additional high-resolution data collected during the pre-design investigation (see Section 5.2). These data were incorporated into the existing 3-D site model (EVS model) used in a complimentary effort to design the placement locations of the VWSs.

The VWSs were designed to yield mass discharge estimates that agree with the results from the EVS model which includes all other available site data. This evaluation is specifically considered in Performance Objective 5.

To understand the amount of pre-design data necessary to support a reliable design, a bootstrapping-type exercise was performed. PFOS mass discharge was calculated using all site data (i.e., 100% of data) and then some data were sequentially removed and PFOS mass discharge was recalculated. The predicted mass discharge values from these alternate designs were calculated and compared. These results are shown in Figure ES-5. The y-axis represents the calculated PFOS mass discharge values for each model normalized to the value from the 100% model. This is a practical approach whereby a relationship between the amount of pre-design data available and the predicted mass discharge measured from the resulting VWS design can be developed. As seen in Figure ES-5, similar PFOS mass discharge values are estimated when 100, 90, 80, and 60% of all available data were used. More significant variation is observed when 40 and 20% of the data are used. This implies that more than enough pre-design data were available to support the VWS design. This performance objective is considered partially achieved because a clear relationship between data used and the calculated mass discharge was developed via a practical method. However, the analysis did not yield results that agreed within ±25% of the mass discharge estimated independently from the other available site data (e.g., on Figure ES-5, below, calculated relative mass discharge values between 0.75 and 1.25). The average results from the HPT, DTS, and SWTT methods yielded results of 1.4, 1.6, and 6 respectively. However, as discussed further in Performance Objective 5, the ±25% target is likely overly and unnecessarily optimistic given the geologic complexities and concentration variability. As such, this performance objective may still be considered achieved.

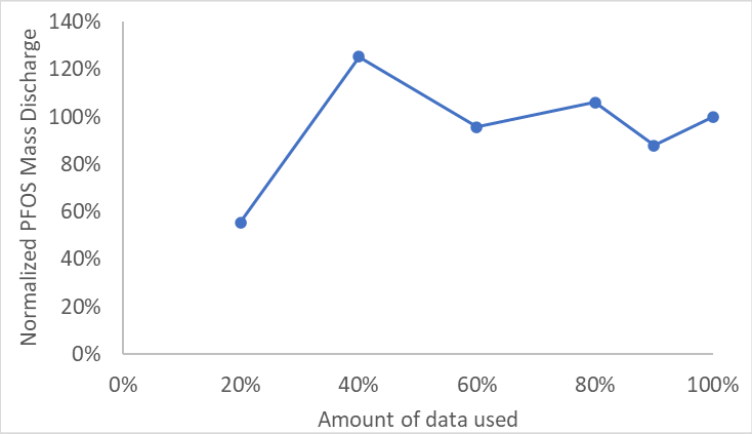

**Figure ES-5. Relationship Between the Amount of Available Data used and Calculated PFOS Mass Discharge**

***Quantitative Performance Objective 5: Validate VWS Application for Quantifying Mass Flux/Discharge Along Transects***

This performance objective is intended to verify the reliability of using VWS transects to measure PFAS mass flux/discharge. Mass flux/discharge normal to groundwater flow were calculated for the transect VWSs using groundwater samples collected from VWS well screens and the different measures of Darcy flux attributed to each of the screen zones (hydraulic testing, point-dilution tracer testing, A-DTS). These estimates were compared to mass discharges estimates developed from

geostatistical modeling of hydraulic conductivity data from conventional vertical borings/wells installed along the same transect (most of these data were developed under prior ESTCP project ER19-5203 and were supplemented with new data collection) and PFAS concentrations measured in VWSs for each performance monitoring event. These analyses were completed in EVS and an example of the calculated PFOS mass flux distribution is shown on Figure ES-6, below (the hydraulic conductivity field is depicted in greyscale and the mass discharge distribution is depicted in color flood with the high values corresponding to warmer colors).

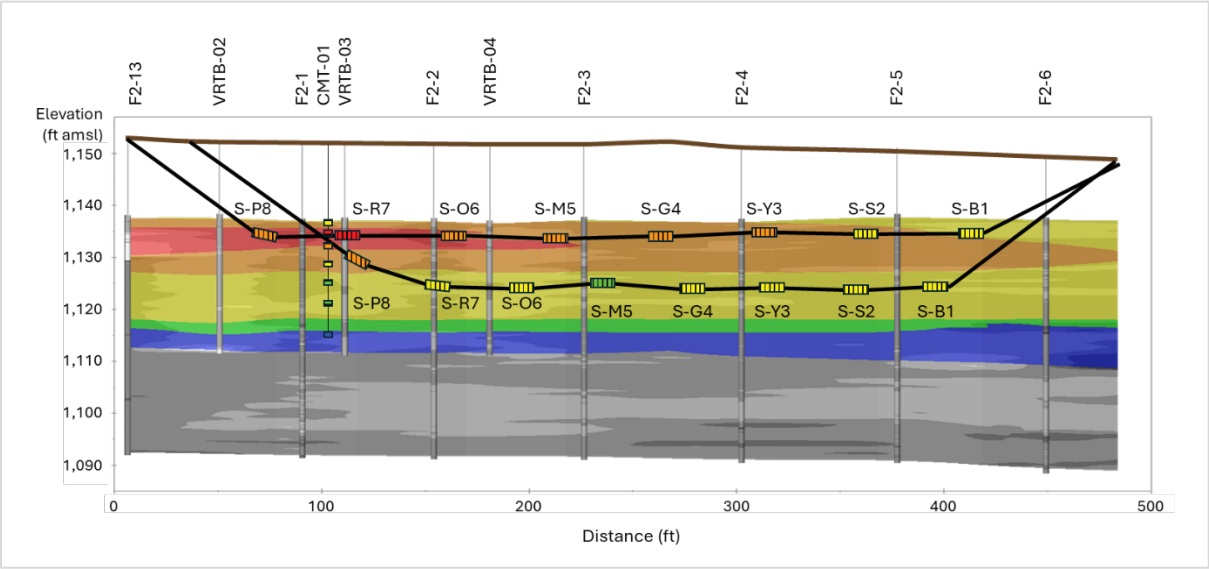

**Figure ES-6. Example EVS Calculated PFAS Mass Flux Distribution for Performance Monitoring Event #2**

The average PFOS mass discharge estimates for each method and for each monitoring event ranged from 58 to 326 mg/day (0.21 to 0.12 kg/year). Although the EVS-based method utilizes the most site geological data it should not necessarily be considered the "gold standard" since its results are highly dependent on geostatistical parameter values and associated data interpolation. This method consistently yielded some of the lowest values, suggesting some other methods (especially SWTT) may provide estimates with a high bias. Regardless, the average results for both the HPT and A-DTS agree with the EVS result within a factor of 2, and all methods fall within a factor of 3 agreement envelope (see Figure ES-7). Furthermore, the event-to-event variability, as measured by the relative standard deviation (RSD) is similar for all of the methods (with EVS being the highest), ranging from 20 to 56%. This implies that the differences in methods are related more toward a systemic consistent bias rather than precision and repeatability. In practice, remediation decisions are not made from specific mass discharge values or single estimates, but rather from trends in mass discharge over time. As such, all methods appear to be reliable for this application. In most cases estimating mass discharge from several methods will increase confidence in estimated values and provide insight regarding uncertainty of the estimates. Overall, the results support the use of VWS for PFAS mass discharge estimation by multiple independent methods.

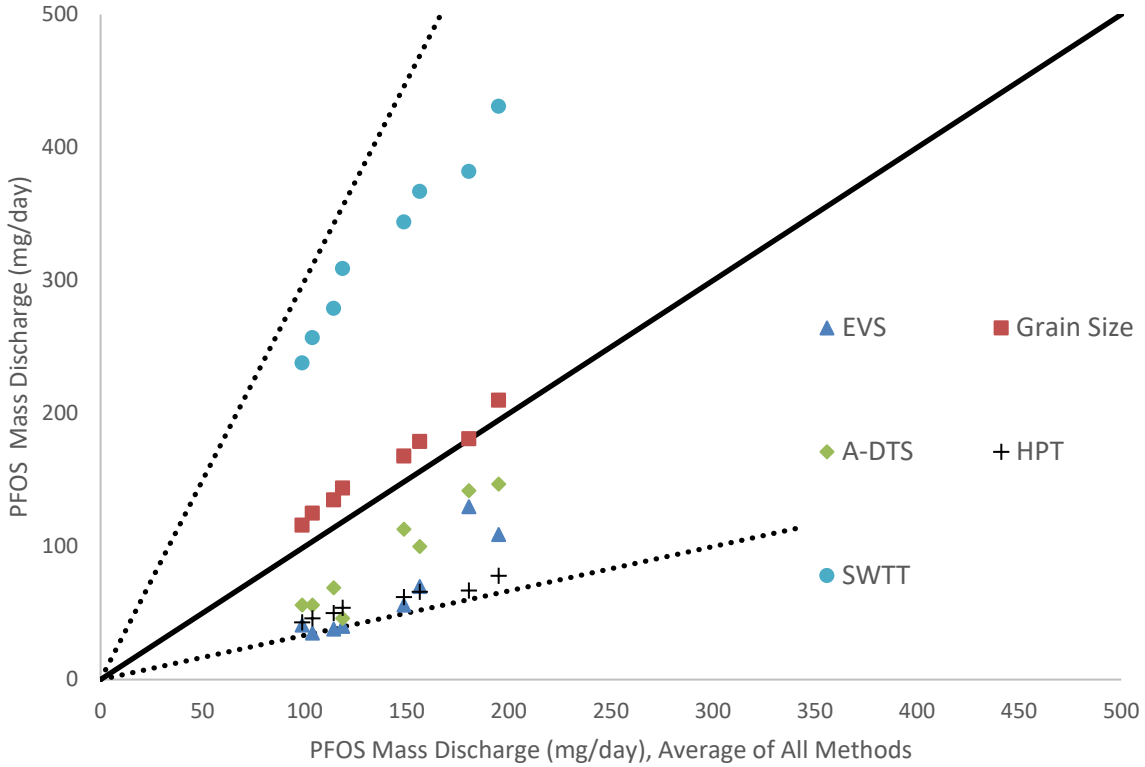

**Figure ES-7. Comparison of PFOS Mass Discharge Estimates for Each Performance Monitoring Event to the Average Value for Each Method.**

*The solid line represents 1:1 correlation and the dotted lines represent an agreement envelope of a factor of 3.*

***Quantitative Performance Objective 6: Verify Material Compatibility with Per- and Polyfluoroalkyl Substances***

This performance objective verified the expectation of PFAS compatibility based on previous published work and assessed the key components of the Vertebrate™ system that are in direct contact with sampled water.

Laboratory-based experiments were completed and focused on key VWS components including the sock polyester geotextile screen wrap, HDPE screen, and HDPE riser tubing. Specifically, rinsate experiments (passing clean water over system components to document no significant PFAS leaching) and soaking experiments (soaking key system components in a known PFAS solution to document no significant PFAS mass loss) were completed.

The criteria for this performance objective are considered achieved. No obvious signs of positive or negative bias that would affect data usability have been identified. Based on the data collected in this study, the VWSs can be tested prior to production for certification to be free of primary PFAS-type analytes. In addition, sorption of PFAS to VWS materials was measured indirectly, and the results did not indicate the VWS materials are a significant sink for PFAS. *Therefore, leaching and adsorption biases are not practical to consider as interference when using VWS and the criteria for this performance objective are considered achieved.*

***Qualitative Performance Objective 1: VWS Can Assess Contaminants and Conditions Along the Flow Path in a Longsect Configuration***

Both the absolute concentrations of PFAS species and their relative abundance (i.e., concentrations of individual PFAS species relative to each other) may change along the flow path due to PFAS transport and fate properties, geochemical conditions, and release/source mechanisms. A longsect VWS configuration that is oriented along a groundwater flow path orientation may be useful for assessing these conditions and monitoring changes through time. This performance objective is intended to assess the feasibility and usefulness of a longsect VWS configuration.

This performance objective was assessed using PFAS concentration data collected from the longsect VWS and compared to data along the flow path collected using vertical data collection methods (i.e., VAP samples and samples from multilevel and conventional wells). An eight-screen 477-foot-long VWS was successfully installed in a longsect configuration along an inferred groundwater flow path from the source area in a south-southeast direction. The average PFOS and PFOA concentrations from the longsect VWS and nearby VAP and conventional vertical monitoring wells were compared. In general, both the PFOS and PFOA data show consistency between the sampling methods and follow a general trend where the first several measurements are similar (approximately 1,100 to 2,700 ng/L for PFOS and 30 to 102 ng/L for PFOA) and then increase by more than 10 times for PFOS (up to 13875 ng/L) and more than 5 times for PFOA (up to 239 ng/L) approximately 240 feet downgradient. Concentrations then decline somewhat at 275 and 310 feet downgradient. Also, the relative concentrations of primary PFAS species along the inferred flow path distance are consistent. The generally consistency of VWS data with other sample types and the smoothness of the trend (i.e., high spatial correlation) suggest the well screens were located approximate along a common flow path and that VWS systems can be used to characterize contaminant concentrations in this way, and to assess contaminant transport processes along the flow path. *As such, the success criteria for this performance objective are considered achieved.* However, this application of VWSs will be more challenged at sites with significant geologic heterogeneity and variable flow direction.

***Qualitative Performance Objective 2: Demonstrate integrity of grout seals to isolate individual screen segments***

This performance objective is intended to confirm the integrity of the grout seals separating each well screen segment of the VWS. Seal integrity prevents groundwater from short-circuiting along the well bore and is necessary for sample quality and reliability as well as reliability of hydraulic tests in the screen intervals. Data from two independent methods were used to assess this performance objective:

A pressure transducer was inserted in VWS screen segments and water was added to adjacent screen segments to detect pressure increases from hydraulic tests in adjacent well screens. No hydraulic response was noted in individual screen segments from pressure changes in adjacent screens. The A-DTS system was used to measure temperature under passive and active (heated) conditions from the well bore. Because the different well materials (e.g., grout seals, sediments) exhibit a contrast in thermal conductivity, the position and continuity of seals along the full VWS length were mappable. Thermal response could be quantified two ways: temperature above background during curing and apparent thermal conductivity from A-DTS test.

Pressure transducer data do not show clear evidence of seal failure or poor seal construction (e.g., immediate increase in pressure greater than 1 foot of head) during injection testing in adjacent screen intervals. The A-DTS data delineate continuous seals that are at least 5 feet long (mean 13 feet, maximum 20 feet) between the five horizontal screens for the shallow VWS. *Overall, grout seals in the horizontal section appear to be placed where intended and are largely functioning as intended (hydraulic separation), as such, this performance objective is considered achieved.*

***Qualitative Performance Objective 3: Identify Challenges and Limitations of VWSs***

This performance objective aims to gather existing practical site implementation and operational considerations to help guide the design of VWSs for monitoring PFAS mass flux/discharge for other sites. Surveys from project personnel involved in installation and system operation, monitoring, sampling, and hydraulic testing were conducted to document implementation challenges or practical considerations throughout the project. Drilling and installation challenges were assessed based on site geologic and hydrogeologic conditions, and experience with the HDD required for the VWS installations.

*This performance criterion is considered successfully achieved because no significant implementation or operational challenges are identified that would limit widespread application of the VWS technology at a broad range of AFFF PFAS sites.* Key lessons learned from this field demonstration include:

- Avoid installing screens at an angle:
- Limit entry/exit angles to prevent tight bends in VWSs.
- Irresolvable uncertainty in confirming as-built vertical borehole location results in a minimum target thickness of 1 to 1.5 feet.
- Currently evaluating alternative grout delivery methods such as a mechanical seal or other means to ensure more precise placement of grout seals.
- Well materials/construction significantly affect hydraulic test results.
- Understanding seasonal water table fluctuations will be important at PFAS sites due to the potential for PFAS to accumulate near the air-water interface. VWS screens installed in high-flux zones near the water table could become dry when groundwater levels decline.

***Qualitative Performance Objective 4: Assess Robustness of the Technology***

This performance objective assesses robustness of VWS components to identify if there are design flaws or limitations that should be addressed before the VWS technology is applied at other AFFF PFAS sites. Feedback was obtained from geologists and field staff regarding observed ruggedness and performance of screens, sampling ports, connections, and other well components. Keuy responses included the following:

- Feeding sampling tubes can be challenging; dedicated tubing is recommended to simplify sampling.
- Specialty fittings are required for tracer and slug tests.

- Tight bends may inhibit flow and should be avoided where the well risers enter the well vaults.
- Based on discussion with drillers it may be possible to obtained geologic information after the pilot borehole has been installed using nuclear magnetic resonance imaging geophysical sonde that is pulled through the borehole (e.g., Spurlin et al., 2019). This could be used to confirm geologic interpretations before final VWS design and installation.

*This performance criterion is considered successfully achieved.* No fundamental design flaws/ limitations were identified, and no systemic problems were experienced during installation and sampling. As of August 2023, more than 200 VWSs have been installed. Lessons learned from previous installations and this ESTCP project will be used to continue improving the design, installation, and sampling processes.

## COST ASSESSMENT

All costs associated with design, installation, and monitoring of VWSs were tracked during the demonstration project. A simple cost model is presented in Table ES-2, below, and serves as general guidance for estimating the costs of installing VWSs. The costs do not include predesign characterization activities or performance monitoring and data analysis because their costs are highly site-specific and dependent on project objectives. For the VWS systems, the model is based on actual costs for this project and assumes three VWSs with a total length of 1,390 feet, eight screens per VWS (for a total of 24 screens), and one stand-alone horizontal fiber optic cable (for distributed temperature sensing [DTS]).

**Table ES-2. Cost Model for Installation of Three VWSs**

| Cost Element – VWS | Data Tracked During the Demonstration | Unit Cost | Unit | Quantity | Cost |
|---|---|---|---|---|---|
| Materials: VWS components | Three VWSs with total length of 1,390 feet. | $103,000 | Lump sum | 1 | $103,000 |
| | Risers and grout lines: 0.75-inch high-density polyethylene (HDPE). | | | | |
| | Well screens: 1-inch-diameter HDPE with geotextile screen. Eight screens per system for total of 24 screens. | | | | |
| | A-DTS fiber optic cables. | | | | |
| | Tracer wire: copper clad steel wire. | | | | |
| Installation of VWSs | Utility locating and surveying. | $105,000 | Lump sum | 1 | $105,000 |
| | Drilling equipment mobilization. | | | | |
| | Drilling, reaming, and well installation. | | | | |
| | Well development. | | | | |
| | Grout well seals. | | | | |
| | Flush-mount vaults. | | | | |
| Waste disposal | Waste characterization: analytical costs. | $3,000 | Lump sum | 1 | $3,000 |
| | Solid and liquid waste disposal: container rental, transportation, disposal. | $30,000 | Lump sum | 1 | $30,000 |
| **Total (VWSs only)** | | | | | **$241,000** |

The costs unique to the VWS are the well materials, with most components made of HDPE. For a typical VWS, the well materials will be roughly 50% of the installation costs (excluding waste disposal for drilling wastes). The cost of well materials have risen during the last couple of years due to high inflation rates and global supply chain issues. It is difficult to predict how material costs will change in the coming years. Most remediation professionals are already familiar with the primary factors that influence vertical drilling costs. Most of these same factors also influence costs associated with the HDD method used to install VWSs. Several variables impact VWS installation costs and each design is customized based on the objectives of the given project. The main cost drivers of the VWS technology are as follows:

- *Number of VWSs*. Unit costs for installation of a single VWS will be higher due to costs of mobilizing the directional drilling rig and associated equipment. The unit costs decrease when installing multiple VWSs.
- *Number of VWS segments and diameter*. A larger number of segments results in higher cost of well materials (dedicated riser and grout lines to each screen), additional time installing grout seals between the segments, more well development effort, and higher waste disposal costs due to the larger volume of liquid waste produced.
- *VWS length and depth*. Well length and depth have a significant impact on the overall installation costs because they strongly affect drilling and materials costs. For longer wells, larger investigation-derived waste (IDW) volumes are generated during drilling and reaming operations.
- *Lithology*. Difficult drilling conditions such as dense soils and cobbles result in slower drilling and therefore higher drilling costs. Drilling through bedrock and formations that are prone to flowing sand conditions (and resultant borehole instability) will also cause costs to increase.
- *HDD navigation*. A walkover locating system is most often used during installation of the VWSs. At some project sites, walkover locating may not be applicable due to electromagnetic interference, lack of access above the drill head, or drilling depth greater than approximately 70 feet. Expanded features for walkover tools have reduced the interference and features like drill-to-box allow some avoidance of commons interference; however, at some sites, interference can require alternatives. In these cases, a more expensive wireline navigation system would be required.

The specific requirements, scale and geometry of each application will vary. However, product capabilities and limitations can provide a typical application scenario and scalability when examining the cost. To start, drilling speed in typical lithologies is approximately 300 to 400 feet per day (ft/day). Thus, a 300- to 400-foot well system can generally be installed in 2 days (1 day for drilling and 1 day for installation and development). Well systems significantly shorter than 300 feet cannot necessarily be installed in considerably less time, and cost per foot increases appreciably. From this point of 300 feet or greater to the maximum length of typical sleeve sizes (800 to 1,200 feet) the costs are approximately linear. Beyond this distance, rig sizes and sleeve changes increase costs significantly. Also, the well screen spacing and screen length are proportional to the plume width and, at these typical spacing distances, are practical and only marginal and linear cost increases are experienced over the total distance. A typical and scalable design with an estimated drilling and materials cost of $150,000 is summarized below (oversight and IDW disposal is excluded as these are varied conditions):

- A site with sandy to silty soils with a water table depth of 10 feet.
- Two VWSs installed with 1,000 feet total of drilling, providing either stacked or multiple transect positions. A total of 20 well screen positions.
- Risers (¾ inch) for probe and tracer access, with a 4-inch sleeve.
- A 20-foot installation depth, with little to no interference for locating tools.
- Standard vaults and finishing requirements.
- Straightforward drilling conditions, with no rock or other obstructions, and standard drilling mud blends.
- Mobilization of drilling equipment within the region.

## IMPLEMENTATION CONSIDERATIONS

VWSs are most advantageous for poorly accessible plumes. The subsurface zones beneath buildings, flightlines, and other operational obstructions, including natural obstructions (e.g., ponds, forested areas) can be accessed from alternate surface positions using this technology. However, for optimal design and to maximize the performance of this technology, the following key pre-qualifications and considerations are suggested:

- The concentrations and lithology of the plume should be well-understood.
- Previous penetrations, well installations, and other vertical environmental equipment should be considered as obstacles for the VWS installation. A buffer distance between the VWS and previous penetrations is recommended at 5 feet or greater.
- Depths greater than 60 feet may require additional setbacks and larger drilling equipment. Depths greater than 100 feet likely will require additional specialized tracking equipment.
- Utilities at the beginning and end of the bore must be properly marked and at known depths anywhere the depth of the bore is less than 10 to 15 feet.
- Walkover electromagnetic drill bit locating is used along the entire bore length; however, interference often exists inside buildings and other obstacles.
- VWSs are custom built and generally require 4 to 8 weeks for processing, construction, and shipping.

# 1.0 INTRODUCTION

This Final Report describes the field deployment and performance monitoring associated with Environmental Security Technology Certification Program (ESTCP) Project ER20-5026. Points of contact (POC) information for key team members involved in the demonstration is provided in Appendix A. The objective of Project ER20-5026 is to field-validate the use of the horizontal multiport Vertebrae™ well system (VWS) for monitoring contaminant mass flux/discharge in groundwater systems. It is increasingly recognized that contaminant mass flux/discharge provides the most representative measure of plume dynamics and risk to receptors. Consequently, remedial technologies focusing on long-term mass flux/discharge reduction will be increasingly favored, and new strategies that can accurately measure changes in mass flux/discharge through time (caused by remediation activities and/or natural attenuation processes) will be more frequently implemented. Flux-focused monitoring approaches are relevant for any type of contaminant source zone but will be particularly important in the future for assessing the risk and benefits of mitigation activities for per- and polyfluoroalkyl substances (PFAS) discharging from fire training areas and other source area types (Figure 1, below).

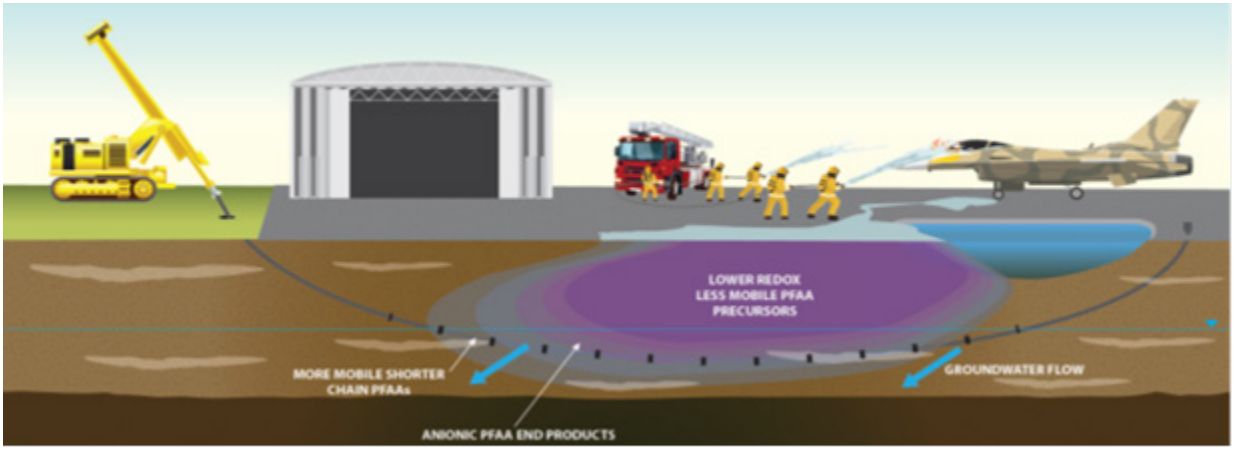

**Figure 1. Conceptual Depiction of a VWS Measuring PFAS Mass Flux/Discharge**

***The overall goal of this project is to demonstrate and validate the Vertebrae™ horizontal well system (VWS) as a technology for reliable long-term monitoring of contaminant mass flux/ discharge from PFAS source zones.***

## 1.1 BACKGROUND

The purpose and scope of this project is to demonstrate the VWS, a next-generation segmented, nested horizontal well technology (Koenigsberg et al. 2018), for monitoring changes in contaminant mass flux/discharge emanating from source zones and high-concentration areas through time. During the past decade, more than 200 VWSs have been installed in the field for general plume monitoring, remediation fluid injections, air sparging, and soil vapor extraction; however, they have not been specifically designed to monitor mass flux/discharge and have not previously been used for PFAS contaminants.

Contaminant mass flux/discharge estimation is challenging because it requires high-resolution measurements of contaminant concentrations and groundwater flux, which can be highly variable spatially due to orders of magnitude variations in concentration and hydraulic conductivity (K) in short distances. Mass flux can also vary through time due to seasonal flow system dynamics, water supply well operations, and remediation activities. Therefore, technologies that provide repeatable, high-resolution mass flux/discharge datasets that can target the important zones within heterogeneous plumes efficiently are needed to optimize remediation performance and determine when to transition to less aggressive technologies and long-term monitoring.

Of the methods that are available to measure contaminant mass flux/discharge, the transect method is probably the most insightful and commonly used because it couples with characterization (Guilbeault et al. 2005; Einarson et al. 2010; Interstate Technology & Regulatory Council [ITRC] 2010; Einarson 2017). The transect approach involves vertically drilled permanent or temporary (i.e., snapshot) installations oriented perpendicular to groundwater flow across a groundwater plume. However, this approach can be costly because it requires many individual vertical boring locations (which requires surface access) given typical high spatial variability in plumes, and many hundreds of feet of drilling with uncertainty in the horizontal direction between vertical locations. This is especially important if the target interval is relatively deep or requires high vertical resolution monitoring or sampling at each location along the transect. Direct contaminant flux approaches such as passive flux meters (Annable et al. 2005; Klammler et al. 2007) are also generally applied at high spatial resolution along transects using vertical deployments.

Further development of the application of the VWS technology will benefit the U.S. Department of Defense (DoD) and the environmental community at large because it will contribute to advancement with both cost and effectiveness in understanding contaminant mass flux/discharge in site assessment, remediation, and monitoring. In particular, the VWS will enable precise and repeatable monitoring of mass discharge with intervals oriented to intersect zones with high concentrations/flux emanating from complex source zones through time, supporting more reliable risk assessment, remedy performance assessment and optimization, and transition from active to passive remedies.

The technology is applicable to any type of groundwater contamination; however, it offers particular potential for monitoring mass discharge changes through time from PFAS sources. Scaled up across the portfolio of DoD sites, this could result in significant total remedy savings through more reliable characterization, risk assessment, flux-based decision making, and better remedy design and operation with improved performance monitoring.

## 1.2 OBJECTIVE OF THE DEMONSTRATION

The overall goal of this project was to demonstrate and validate the VWS as a technology for reliable long-term monitoring of contaminant mass flux/discharge from contaminant source zones. More specifically, this project was intended to:

- Adapt and apply mass flux/discharge methods proven for conventional vertical transect approaches to the VWS.
- Compare VWS mass flux/discharge results and changes through time to a conventional vertical transect approach.

- Potentially evaluate longsect VWS orientation to assess changes in PFAS composition along the plume flow path.
- Develop guidance regarding the VWS technology application, limitations, anticipated performance, design considerations, and cost.

## 1.3 REGULATORY DRIVERS

It is increasingly apparent that contaminant mass flux and mass discharge represent the most appropriate measure of plume dynamics and risk to receptors. Consequently, remedial technologies focusing on long-term mass flux/discharge reduction will be increasingly favored, and Strategic Environmental Research and Development Program (SERDP) and ESTCP have funded numerous projects to develop flux-focused characterization and remediation techniques. New strategies that can be used to more accurately measure changes in mass flux/discharge through time will be developed and more frequently implemented in the future (Klammler et al. 2007; Suthersan et al. 2010; Acar et al. 2013; Klammler et al. 2016; Horneman et al. 2017; Horst et al. 2022; Divine et al. 2023). In 2018 and 2022, SERDP and ESTCP hosted strategic workshops attended by personnel representing DoD remedial program managers, federal and state regulators, academic researchers, industry representatives, and consultants focused on the remaining challenges for chlorinated solvent and PFAS remediation. The summary reports from these workshops (SERDP and ESTCP 2018, 2022) identify methods for evaluating mass discharge to support closure as a critical demonstration need, noting:

> *"Mass discharge data can provide considerable insight into the benefits of remediation efforts, the strength of residual sources, and the risks to downgradient receptors of concern. The results can be valuable in prioritizing residual sources for further treatment, evaluating whether to transition to MNA, or whether site closure is warranted. There is a need to develop and demonstrate methods and approaches to characterize the mass discharge of contaminants from residual sources and use that information to make a robust evaluation of the risk posed by the residual source to groundwater quality near source areas and to downgradient receptors."* (SERDP and ESTCP 2018)*."*[1]

As noted by Anderson (2021), many regulatory agencies are currently publishing criteria intended to define the nature and extent of PFAS-impacted environmental media. However, the simplfying assumptions supporting the calculation of some of these screening values may not appropriately reflect multiple complex and rate-limited processes (e.g., hydrophobic interactions with soil organic carbon, electrostatic interactions with the surfaces of clay minerals, and air-water interfacial accumulation) controlling PFAS transport, particulary in the vadoze zone near source areas and within the capillary fringe. Because reliable simulation of PFAS transport in field settings appears to require complex multiprocess kinetic models with multiple input parameters that will be difficut to constrain, reliable methods for long-term monitoring of PFAS mass flux/dischare will be required at many sites to assess risk, determine remediation enpoints, and assess remedy performance (SERDP and ESTCP 2022; Horst et al. 2022).

[1] MNA = monitored natural attenuation.

# 2.0 TECHNOLOGY

This section provides an overview of the VWS, which has been deployed at more than 70 sites. The focus for this project is its use for long-term monitoring of PFAS mass flux/discharge in groundwater, which is a new and unique application for this technology.

## 2.1 TECHNOLOGY DESCRIPTION

The VWS is a single, small-diameter horizontal well that contains multiple isolated screen segments; essentially, it is an engineered multiport well that is installed horizontally instead of vertically (Figure 2, below). The VWS can provide another transect method option, as a complement or alternative to the conventional vertical transect option. The VWS is unique, with many discrete screen zones running horizontally along its length and separate, small-diameter tubing plumbed from each screen to the surface. Grout, which is tremied in, is used to isolate the individual tailor-designed screen intervals. The VWS technology can be applied as a variation of the conventional transect approach. The difference is the monitoring points are installed horizontally instead of vertically, with improved coverage along the width of the plume at targeted depths with highest concentrations or flux, but with generally lower vertical resolution due to practical limits on placing multiple systems at different depths. The VWS approach is novel and advantageous because multiple closely spaced measuring points across a transect can be easily installed from a single boring (reducing costs) and contaminant zones that may have been previously inaccessible via vertical boreholes can be characterized. Currently, detailed geologic information is not readily available during the drilling process; therefore, an accurate understanding of contaminant distribution within the site hydrostratigraphy from high-resolution characterization using vertical borings/profiles is required to optimize placement of the horizontal wells and to select target intervals for the monitoring zones.

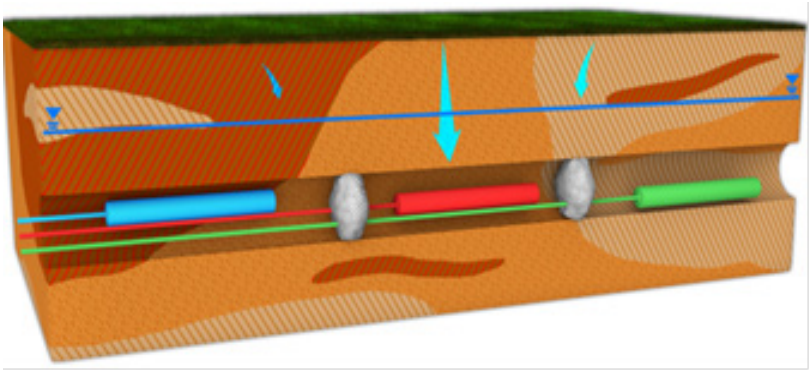

**Figure 2. VWS**

*The VWS contains multiple screen segments separated by grout seals with independent connections to the surface. It can be thought of as a nested well installed horizontally.*

The conventional transect method for characterizing contaminant mass flux relies on a series of temporary or permanent vertical monitoring points providing data in vertical profiles along a transect across the entire plume, perpendicular to groundwater flow (ITRC 2010). The monitoring points are sampled to provide concentration data across the control plane at appropriate lateral and vertical spacing to capture the plume concentration distribution.

An appropriate method for measuring groundwater flux at similar high resolution is also required and the combined groundwater concentration and flux data are used to assess contaminant mass flux/discharge across the transect (note: this does not capture sorbed mass within the plume, which can be significant in many lithologies and relevant to site management decisions).

VWSs are installed using horizontal directional drilling (HDD), which is a mud rotary drilling process that uses a specialized rig and asymmetric bit to drill a curved borehole along a pre-determined bore path and the prefabricated VWS is pulled into the borehole (Figure 3, below). The VWS is a multiport horizontal well that has been installed with as many as 18 discrete screen zones; however, these values are not upper limits because additional screened zones are feasible. To date, VWS wells exceeding 900 feet long and 45 feet deep have been installed, but longer and deeper wells with currently available drilling technology are feasible.

The VWS can be thought of as a nested well installed horizontally instead of vertically. Individual screen lengths range from 3 to 30 feet with separate 0.5- to 1.5-inch-diameter tubing plumbed from each screen to the surface. Multiposition monitoring along horizontal paths can be more efficient because it is aligned with hydrologically significant zones within and at the boundaries of aquifers parallel to layering typical of sedimentary facies. Grout is used to isolate the individual screen intervals within the horizontal well (Figure 2, above). EN Rx, Inc. (EN Rx) has developed a proprietary grout seal mixture to increase elasticity, longevity, and sealing efficiency to isolate the intervals in each horizontal boring. The VWS is compatible with all common contaminant types and has been used at sites with petroleum hydrocarbons, chlorinated solvents, metals, and high salinity. This was the first site where the VWS was deployed for monitoring PFAS. Prior to installation, all well system components were demonstrated to be PFAS-free (further discussed in Section 7.6 as part of Quantitative Performance Objective #6).

**Figure 3. Installation of VWS**

*Left: Horizontal directional drilling and mud pit. Middle: Asymmetric drill bit. Right: Preconstructed VWS immediately prior to pullback into the borehole.*

## 2.2 TECHNOLOGY DEVELOPMENT

During the past two decades, HDD methods have been used in a wide range of environmental applications and the drilling technology has been completely developed and is readily available throughout the United States. Lubrecht (2012) highlights some of these applications and notes some key sustainability advantages of HDD compared to conventional vertical drilling techniques.

The VWS, which is a patented technology developed by EN Rx, was first implemented in a field application for remediation agent injection purposes in 2014 and the first system used to collect groundwater quality data as a monitoring system was completed in 2015. To date, more than 205 VWSs have been deployed at more than 70 sites in a wide range of geologic settings in which more than 1,100 individual wells (separate screen intervals) were installed. The wells were installed to characterize contaminant distribution and support remediation. VWSs have not previously been used to quantify contaminant mass flux/discharge; this project was specifically intended to demonstrate and validate this application. No technology development was conducted under the ESTCP project prior to the field demonstration.

## 2.3 ADVANTAGES AND LIMITATIONS OF THE TECHNOLOGY

Compared to vertical wells, horizontal wells offer several notable advantages in environmental remediation applications, as detailed by others (Lubrecht 2012; Koenigsberg et al. 2018; Divine et al. 2018a, 2018b; Laton 2019). Horizontal wells can be readily installed and operated under buildings, roads, flight lines, and other surface infrastructure, and therefore represent minimal potential to impact facility operations during installation and sampling. Horizontal wells can be designed to target precise elevations and laterally continuous high-permeability zones in the horizontal plane (e.g., sand layers). VWS wells can be constructed with up to approximately 20 individual and separate well screen segments separated by as little as 10 feet, allowing high spatial resolution of groundwater concentrations and surgical targeting of treatment zones. Based on reasonable assumptions, a single VWS may be more cost effective than multiple conventional vertical wells when the total number of targeted sampling intervals is more than six to eight for common site conditions.

One of the most important limitations with the VWS technology is that it is not a primary characterization technology because lithologic information is not obtained during directional drilling. Therefore, optimal design of VWSs requires pre-characterization with high-resolution vertical techniques to select the target depths and zones for horizontal screen placements. Heterogeneous lithologies with highly interbedded or discontinuous flux zones may present site-specific implementation challenges. For many sites, it may only be practical to install VWSs at no more than three different depth intervals along a transect, which may limit the amount of vertical characterization possible for complex plumes. Further, understanding seasonal water table fluctuations is important because a decline in groundwater elevation during a dry period could result in a VWS well installed near the water table going dry. This is an important consideration due to the potential for PFAS to accumulate near the capillary fringe because many PFAS tend to accumulate at air-water interfaces (Brusseau 2021; Brusseau and Guo 2022). Additional potential complications that may be encountered during implementation that must be considered include electromagnetic interference with walkover locating borehole navigation system and the inadvertent drilling fluid returns to ground surface along preferential pathways. Qualitative Performance Objective #3 (further discussed in the Section 7.9) was specifically intended to identify challenges and limitations, and associated mitigation measures.

# 3.0 PERFORMANCE OBJECTIVES

Multiple VWSs, each comprising multiple sampling ports at discrete intervals, were installed at a DoD site where monitoring contaminant mass discharge from a PFAS source zone is a priority. Two VWSs were installed transverse to groundwater flow (i.e., transects) downgradient of a PFAS source area. These transverse alignments were located at the same lateral distance from the source area but at two different depth intervals. An additional application was tested with the orientation of a VWS parallel to groundwater flow (i.e., longsect) to measure changes in contaminant characteristics along the contaminant flow path (i.e., plume centerline) within a continuous hydrostratigraphic zone.

Quantitative and qualitative performance objectives were established in the Demonstration Plan (Divine et al. 2021c) to provide the basis for evaluating the performance and costs of the VWS technology. The specific performance objectives, criteria that were used to evaluate success, and a summary of the results are presented in Table 1, below. Detailed evaluations of each performance objective are presented in Section 7 Performance Assessment.

**Table 1. Performance Objectives**

| Performance Objective | Data Requirements | Success Criteria | Success Criteria Achieved? |
|---|---|---|---|
| **Quantitative Objectives** | | | |
| 1. Accurate and reliable placement of screens in subsurface. | Bore-path drilling navigation data, and post-installation geophysical survey data. | Eighty percent (%) of all drilling navigation data agree within 1.5 foot (elevation) of the bore path elevation and 80% of the as-built data agree within 1.5 foot of the planned target depth elevations. | **Yes** Six of six screens along horizontal section were within 1.5 vertical feet of the target elevations and positions. |
| 2. Validate methods for groundwater flux measurement with VWSs. | Hydraulic conductivity, hydraulic gradient, tracer test data, active fiber optic distributed temperature sensing (A-DTS) data. | Complete successful field testing of methods. For each method estimates that are repeatable (±25%) and agree with the averages from all the methods within 25% according to an analysis of variance statistical test (within 25% at an 80% confidence). | **Yes** Both the A-DTS and single-well tracer test (SWTT) methods are considered to have achieved success for this performance objective, based on modified criteria. |
| 3. Assess comparability of samples collected from VWS screens to grab samples. | Concentration data from VWS screens and co-located vertical cores/wells or groundwater grab samples. | Perfluorooctanoic acid (PFOA) and perfluorooctane sulfonate (PFOS) concentrations measured from the VWS screens agree within 1 order of magnitude for at least 75% of co-located grab samples. | **Yes** Sample results from the VWS are consistent with conventional sampling methods. |

## Table 1. Performance Objectives (Continued)

| Performance Objective | Data Requirements | Success Criteria | Success Criteria Achieved? |
|---|---|---|---|
| 4. Demonstrate method to identify appropriate mass flux zones to target VWS placement. | All currently existing hydraulic, hydraulic profile tool, and groundwater grab sample concentration data as well as additional high-resolution data developed during the pre-design investigation. | Achieved if a relationship between pre-design data availability and the predicted mass discharge measured from the resulting VWS designs can be developed, and if this relationship indicates the VWS design will yield a mass discharge estimate within ±25% of the estimated derived from other data. Related guidance for design of VWS from site data will be developed. | **Partially** A clear relationship between data used and the calculated mass discharge was developed via a practical method. However, the analysis did not yield results that agreed within ±25% |
| 5. Validate VWS application for quantifying mass flux/discharge along transects. | Mass flux/discharge estimates normal to groundwater flow for VWSs and conventional vertical borings/ wells installed along a nearby transect. These estimates will be derived from PFAS concentration data and darcy flux values determined from hydraulic testing, tracer testing, the A-DTS. | Mass flux/discharge estimates with VWSs agree with conventional approaches within 25% with equal or lower uncertainty estimated through propagation of uncertainty statistical techniques. | **Yes** None of the methods meet this statistical level, however, this may have been an unrealistic success criterion. The average results for both the HPT and DTS agree with the EVS result within an order of magnitude and event-to-event variability is similar for all of the methods. This implies that the differences in methods are related more toward a systemic consistent bias rather than precision and repeatability. Consequently, the results support the use of VWS for PFAS mass discharge estimation. |
| 6. Verify materials' compatibility with PFAS. | Rinsate blank and PFAS stock solution samples after contact with VWS components. | PFOS and PFOA are less than the United States Environmental Protection Agency (USEPA) Maximum Contaminant Levels (MCLs) of 4.0 nanograms per liter in rinsate blank samples and PFAS loss from the sample due to sorption to well materials is less than 10% or the analytical precision (whichever is greater) for each tested compound. | **Yes** The VWSs can be tested prior to production for certification to be free of primary PFAS analytes. |

## Table 1. Performance Objectives (Continued)

| Performance Objective | Data Requirements | Success Criteria | Success Criteria Achieved? |
|---|---|---|---|
| **Qualitative Objectives** | | | |
| 1. VWS can assess contaminants and conditions along the flow path in a longsect configuration. | Contaminant concentrations data from longsect VWS, monitoring wells, and vertical aquifer profile samples. | PFAS concentration data collected from different screen intervals located progressively downgradient follow discernable and consistent trends, indicating the samples represent locations along a constant flow path. | **Yes** Samples from the VWS were generally consistent with other sample types and exhibited high spatial correlation. |
| 2. Demonstrate integrity of grout seals to isolate individual screen segments. | Pressure data from injection tests and A-DTS temperature data measured under passive and active (heated) conditions. | Pressure data do not show clear evidence of seal failure and A-DTS data delineate continuous seals that are at least 5 feet long between each well screen. | **Yes** Grout seals in the horizontal section are placed where intended and are largely functioning as intended (hydraulic separation). |
| 3. Identify challenges and limitations of VWSs. | Feedback from drillers, installation, and monitoring personnel and project technical staff. | Challenges and limitations are understood and can be readily mitigated. | **Yes** No implementation or operational challenges were identified that would limit widespread application. |
| 4. Assess robustness of the technology. | Feedback from geologists and field staff regarding observed ruggedness and performance of screens, sampling ports, connections, and other well components. | No fundamental design flaws/limitations identified, and no systemic problems experienced during installation and sampling. | **Yes.** |

# 4.0 SITE SELECTION AND DESCRIPTION

Based on the evaluation presented in the Site Selection Memorandum (Divine et al. 2021a), the field demonstration was performed at Grayling Army Airfield (GAAF) in Grayling, Michigan. The combination of site characteristics, previous PFAS characterization, and synergy with the planned remedial investigation (RI) meet the requirements of the demonstration and provide value to the Army National Guard (ARNG) in evaluating the source and nature of the highest PFAS concentrations migrating off site. The mass-flux-based conceptual site model (CSM) will aid in developing future remedy strategies. It is possible that the VWSs could be used to evaluate performance of future technology demonstrations designed to treat the soils and groundwater in this area. Site selection screening criteria presented in Table 2, below, are based on the features and requirements of the VWS and the performance objectives of the demonstration.

**Table 2. Site Selection Screening Criteria**

| Screening Criteria | GAAF |
|---|---|
| Well-characterized PFAS source and plume with high-resolution site characterization (HRSC) data | RI activities initiated in 2019 resulted in a sound CSM and will continue to generate additional relevant data. |
| Previous mass flux/discharge evaluation completed | Detailed mass flux estimate completed as part of ESTCP project ER19-5203. |
| Total PFAS concentrations are relatively high, with several different PFAS constituents present | At least nine PFAS constituents detected in groundwater with total PFAS concentrations exceeding 30 micrograms per liter (µg/L). |
| Aquifer is shallow (plume depth less than 60 feet preferred), relatively permeable, with low variability in K values | Depth to water is 12 to 15 feet below ground surface (bgs). The aquifer exhibits generally low heterogeneity, with K values typically ranging from 30 to 75 ft/day, with some zones that may exceed 200 ft/day. |
| Unconsolidated geologic setting amenable to direct-push techniques for vertical characterization | Unconsolidated glacial sediments. Prior direct-push investigations completed (ESTCP ER19-5203). |
| Ideal if mitigation actions have recently been completed or are likely soon to be implemented | Future source area mitigation actions likely. |
| Straightforward drill rig access | No access limitations. |
| Engaged/supportive regulatory agency and stakeholders | Very supportive. Stakeholders strongly desire the demonstration and believe the results will support the current RI and aid in future decision making and performance monitoring. |

The VWS is appropriate for any contaminant type and has significant potential for chlorinated solvent and PFAS sites. With the DoD's current priority of developing methods to assess risks associated with PFAS discharging from fire training areas, it was recommended that the field demonstration be completed at a PFAS site. Further, although the VWS technology is suited for installation below surface obstructions, for this demonstration the source and plume areas of interest (AOIs) were unobstructed so that transects of vertical cores and application of direct-push profiling methods to inform multilevel well positions could be installed for comparison/validation purposes.

## 4.1 SITE LOCATION AND HISTORY

Camp Grayling is located approximately 200 miles northwest of Detroit, Michigan in the north-central portion of the Lower Peninsula and approximately 80 miles south of Michigan's Upper Peninsula (Figure 4, below). It is the main training facility for the Michigan National Guard and is the Army National Guard's largest facility. The facility occupies 147,000 acres and is divided into North and South Post operational areas.

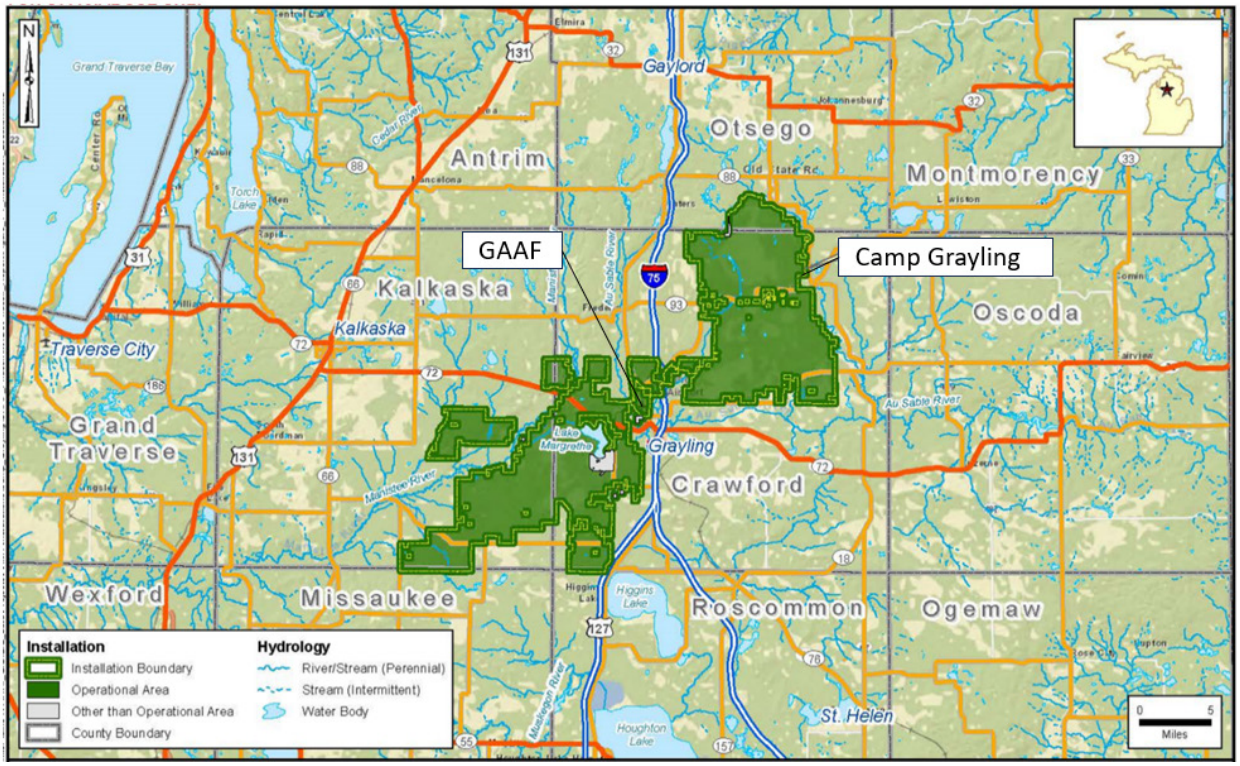

**Figure 4. Location of Camp Grayling**

The focus of this field demonstration was the GAAF (Figure 5, below). The GAAF is located between the North and South Posts of Camp Grayling and has been operational since 1942. The GAAF is located immediately west and northwest of the city of Grayling, at the intersection of I-75 and North Down River Road West and covers 923 acres of state and federally owned property. The general geographic coordinates for the center of the airfield are 44°40′49″N; 84°43′44″W. The GAAF has two runways, and facility access is restricted by controlled gates. The GAAF has support buildings and facilities along its eastern boundary including a control tower, barracks, vehicle storage, and the Camp Grayling Fire Department. The former location of the Camp Grayling Maneuver Area Training Equipment Site (MATES) is on the southwestern portion of the airfield, which is now known as the Former Bulk Fuel Storage Area. The former MATES was historically served by railroad tracks running along the western boundary of the airfield (AECOM 2019).

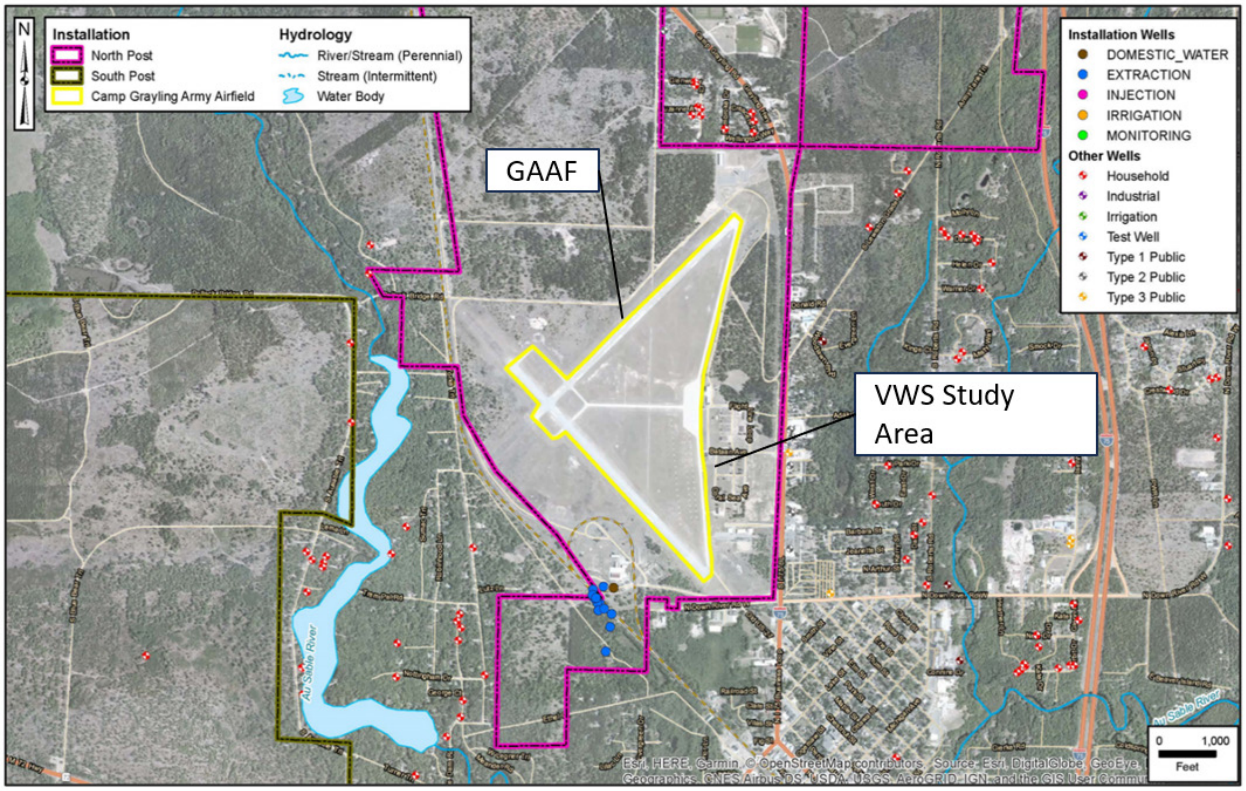

**Figure 5. GAAF**

The predominant land use outside the camp boundaries is public lands, primarily forested. Private lands and residences abut portions of the GAAF, including the city of Grayling, located southeast of the GAAF. Seasonal and permanent residences are present along the banks of the Au Sable River and Lake Margrethe, and both waterbodies are used for recreational activities (e.g., swimming, canoeing, fishing). The city of Grayling and Grayling Township have light industrial and heavy industrial zoning. Reasonably anticipated future land use is not expected to change from the current land use described above (AECOM 2018).

## 4.2 SITE GEOLOGY AND HYDROGEOLOGY

The geology at the GAAF consists of unconsolidated glacial sediments underlain by bedrock from the Coldwater and Michigan Formations. Glacial sediments consisting of sand and gravel outwash plains, lacustrine clay, and glacial till are reported to extend to at least 600 feet bgs. Fluvial deposits associated with the Au Sable River are also present at GAAF (AECOM 2018). Soil borings completed to a depth of 60 feet bgs show soils consisting of well-sorted sand and gravels with discontinuous silty sand layers (AECOM 2018; Figure 6, below). Lenses of clay are also encountered throughout the southeast corner of the GAAF.

**Figure 6. Photographs of Drill Core (Collected from 15 to 20 bgs; left) and Excavation Cut (Right) at the GAAF**

*These images show the relatively coarse and uniform grain size characteristics of the shallow soils at the GAAF.*

Regional and local groundwater flow appears to generally follow surface water drainage patterns. Regional groundwater divides most likely correlate to the major surface water divides for the Manistee, Au Sable, and Muskegon Rivers. The GAAF is located between the main stem and East Branch of the Au Sable River. Groundwater occurs at depths of approximately 6 to 15 feet bgs in unconfined sandy aquifers. A groundwater potentiometric surface map (Figure 7, below) suggests that apparent average groundwater flow direction within the GAAF is southerly, turning southeasterly in the southeast portion of the GAAF toward the East Branch of the Au Sable.

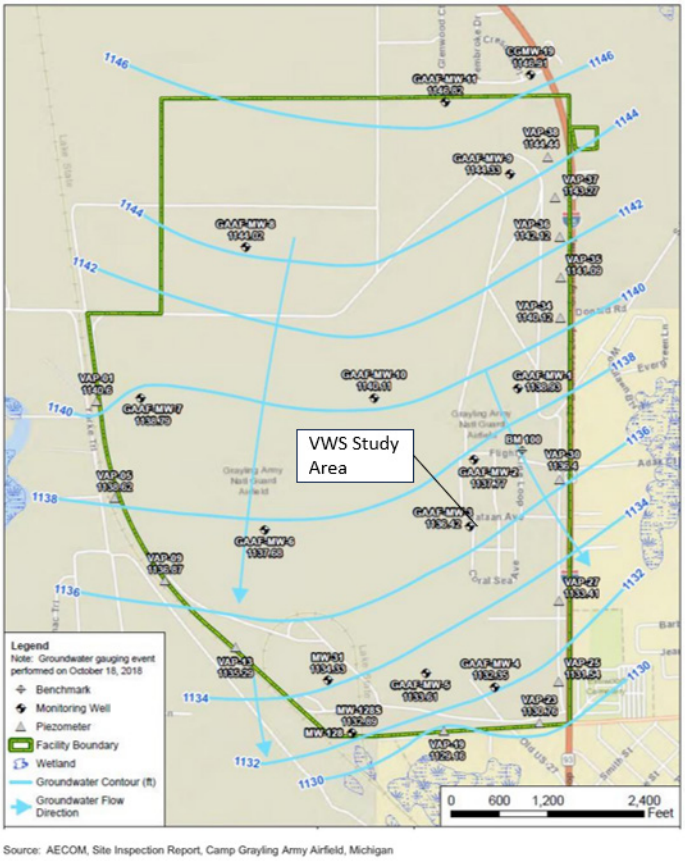

**Figure 7. GAAF Groundwater Elevation Contour Map**

## 4.3 PREVIOUS PER- AND POLYFLUOROALKYL SUBSTANCES CHARACTERIZATION

This section summarizes the PFAS characterization activities that were conducted prior to this ESTCP demonstration.

### 4.3.1 2017 to 2018 Site Investigations

A PFAS investigation was conducted in 2017 by the Michigan Department of Military and Veteran Affairs in the area of the Former Bulk Fuel Storage Area. This area (formerly referred to as the MATES) has an inactive groundwater pump and treatment system (air stripper) to remediate a tetrachloroethylene and trichloroethylene plume and includes a network of monitoring wells associated with the remediation system. The PFAS investigation was conducted in the area of the inactive treatment system and along the site boundary. Based on vertical aquifer profile (VAP) groundwater samples collected along the site boundary, the sum of PFOS and PFOA concentrations detected in VAP samples exceeded the then-current USEPA Health Advisory Limit (HAL) of 70 nanograms per liter (ng/L) at six locations spanning the southern portion of the eastern site perimeter, with the highest concentrations focused at VAP-27 (perfluorooctane sulfonate [PFOS]/ perfluorooctanoic acid [PFOA]: 2,650 ng/L), with concentrations an order of magnitude less to the north and south of VAP-27 (AMEC Foster Wheeler 2017).

Beginning in 2017, the Michigan Department of Environmental Quality (MDEQ) conducted residential drinking water well sampling, which to date has identified 17 wells with concentrations that exceed the USEPA HAL.

In 2018, AECOM conducted a preliminary assessment (PA) to identify and assess potential PFAS release areas at Camp Grayling, including the GAAF. Five AOIs were identified for the GAAF during the PA where PFOS/PFOA in the form of aqueous film-forming foam (AFFF) had been used or had been historically released (AECOM 2018).

In 2018, a site inspection (SI) was conducted to assess the AOIs identified in the PA. In the southeast portion of the GAAF, upgradient of VAP-27, the SI identified PFOS concentrations of 27 and 74 micrograms per kilogram (µg/kg) in vadose zone soil samples collected on the west side of Building 1160, as well as a PFOS concentration of 344 ng/L in groundwater on the east side of Building 1160 (AECOM 2019). Relatively low concentrations of PFOS (2 to 13 µg/kg) were detected in soil on the east side of Building 1195; however, PFOS concentrations in groundwater samples from this area were less than laboratory detection limits (AECOM 2019).

### 4.3.2 Environmental Security Technology Certification Program 2019 Mobile Lab Demonstration and Mass Flux Assessment

In 2019, an ESTCP demonstration project (ER19-5203; Arcadis U.S., Inc. [Arcadis] 2020) was completed to validate the application of real-time mobile laboratory methods for characterization of PFAS sources and associated groundwater plumes. The overarching goal for the analytical chemistry work was to demonstrate that PFAS mobile laboratory methods can be applied in the field to provide near real-time characterization data, allowing adaptive delineation and development of flux-based CSMs.

The mobile laboratory was deployed as part of an adaptive investigation for the southeast portion of the GAAF. The investigation focused on the area associated with two identified AFFF source areas identified at Buildings 1160 and 1194/95. The stratigraphic flux approach (Arcadis 2017) was applied on site, combining real-time high-resolution measurements of stratigraphy and permeability with high-frequency soil and groundwater sampling to focus on characterizing source strength, contaminant leaching, and downgradient mass movement. Validation of the mobile laboratory included adaptive high-frequency soil and groundwater sampling in the source areas (Buildings 1160 and 1194/95) and on transects downgradient progressing toward the southeast site perimeter and boring VAP-27.

The investigation included initially planned borings designated as "primary" and additional borings designated as "adaptive" based on the real-time analytical results. High-resolution permeability measurements were completed using the Geoprobe® hydraulic profile tool (HPT) and were compared to soil descriptions and to K derived from correlation equations based on soil grain-size analysis.

The final locations of the source areas and scope of work for each boring are shown on Figure 8, below. The components of the investigation were as follows:

- Three primary source borings installed immediately downgradient of each of the two potential source areas (Buildings 1160 and 1194/95). Soil samples were collected from the capillary fringe, at the water table, and just below the water table. Groundwater samples were collected via 1-inch-diameter polyvinyl chloride (PVC) temporary monitoring wells with 5-foot-long screens.
- Three adaptive flux transects spaced downgradient of the two potential source areas and upgradient of the highest PFAS concentration area identified at the site perimeter during previous site characterization (VAP-27). Transect locations were completed using HPT borings, VAP sampling, and soil logging and sampling.
- Six secondary source borings completed near Building 1160 to provide greater resolution of source area impacts. Secondary source locations were completed using HPT borings and soil logging and sampling. In addition, VAP groundwater samples were collected below the Building 1160 source area.
- Installation of four lysimeters and synthetic precipitation leaching procedure sampling to characterize soil moisture and contaminant loading in the source vadose zone.

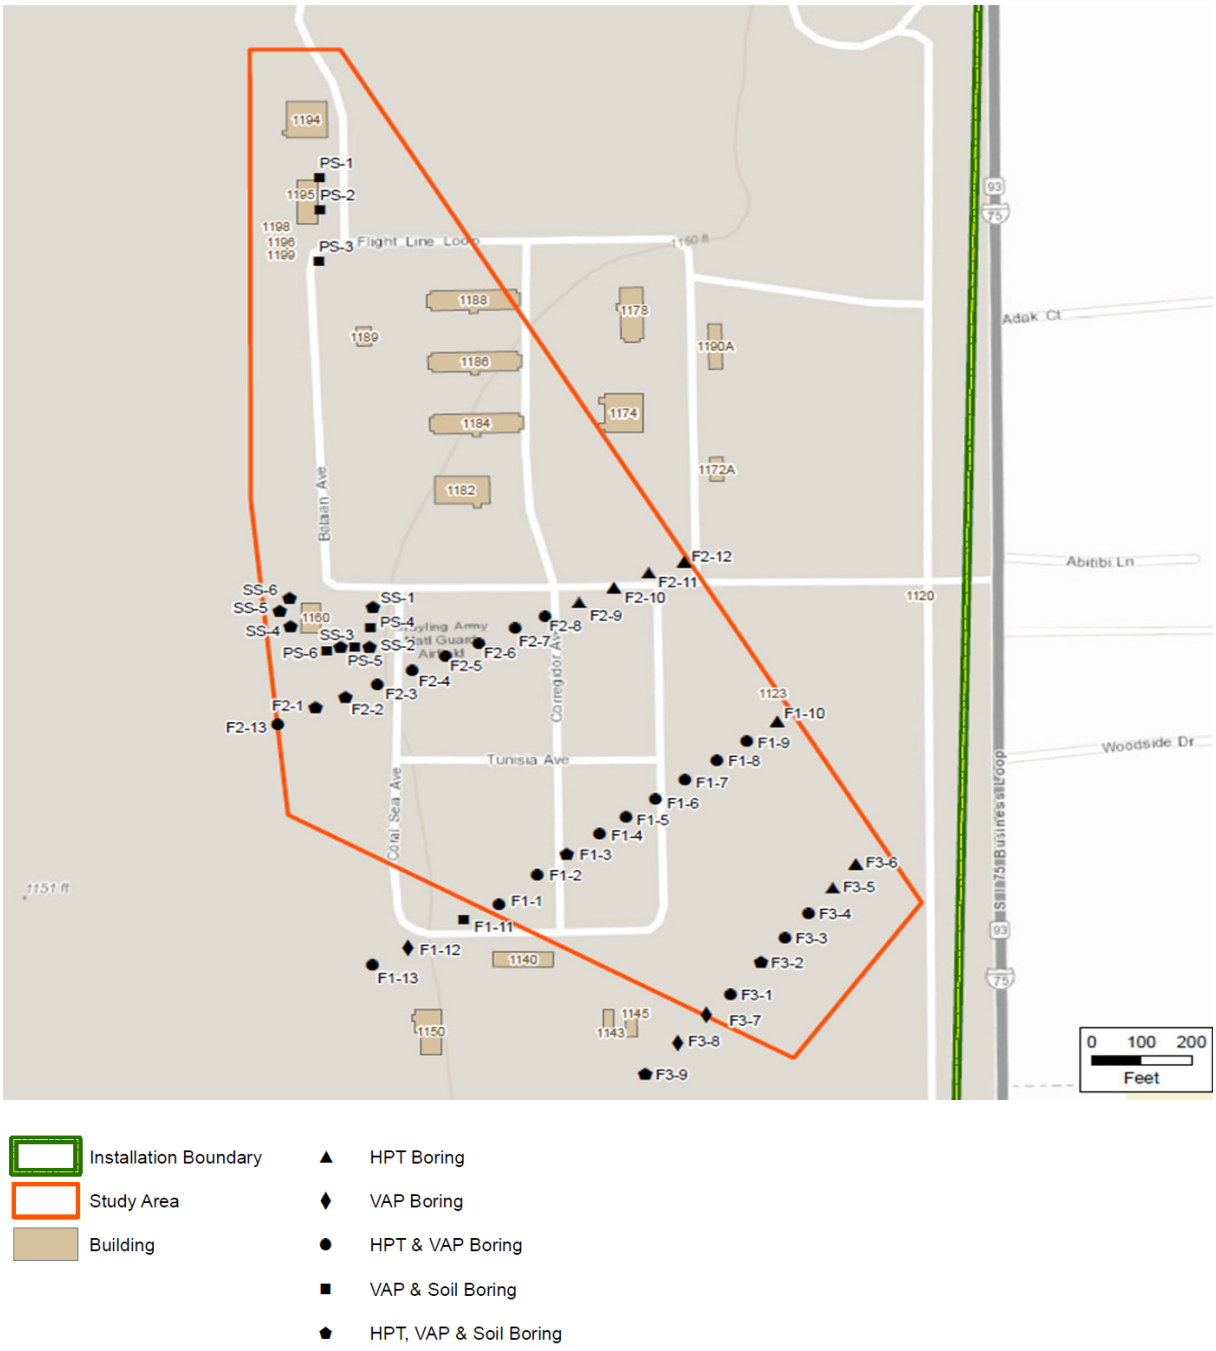

**Figure 8. HPT Boring and VAP Locations at GAAF Completed as Part of ESTCP Project ER19-5203**

Of the PFAS detected at the GAAF, PFOS is dominant in soil and groundwater and was generally detected at concentrations 1 to 2 orders of magnitude greater than perfluorohexanesulfonic acid (PFHxS), PFOA and other PFAS. Rather than focus on delineation, the objective of this project was to define source strength (primarily associated with Building 1160) and identify the primary zones of mass flux downgradient of the source areas along the three HPT/VAP transects.

As the investigation progressed, and based on the mobile laboratory results, the focus of the investigation shifted to Building 1160. In general, the proximity of Building 1160 provided a clearer correlation of source concentration to downgradient mass flux. Only the primary borings were completed at Building 1194/95.

The highest PFOS concentrations in soil at Building 1160 were observed in vadose zone and capillary fringe soils in soil borings SS-4, SS-5, and SS-6, located on the west side of Building 1160 in the area associated with former fire truck parking. The highest concentrations of PFOS were observed in vadose zone soils, up to 560,000 nanograms per kilogram (ng/kg), at a depth of 5.5 to 6.0 feet bgs at boring SS-6. Elevated concentrations were also observed at the capillary fringe and just below the water table with total concentrations (soil/groundwater) up to 95,000 ng/kg at boring SS-5. The PFOA concentrations were typically 2 to 3 orders of magnitude less than PFOS at Building 1160, with a maximum concentration in soil of 9,100 ng/kg detected at a depth of 3.5 to 4.0 feet bgs at boring SS-5. Concentrations of both PFOS and PFOA are significantly less in soils to the east of Building 1160.

Concentrations in groundwater beneath the Building 1160 source area were highest at the water table, with a maximum PFOS concentration of 2,400, 800, and 2,100 ng/L at borings SS-4, SS-5, and SS-6, respectively. Groundwater concentrations within the Building 1160 plume core increase downgradient, with PFOS up to 31,000 ng/L at Transect 2, located 250 feet southeast of the Building 1160 source area. At Transect 1 located 500 feet further to the southeast, PFOS concentrations up to 30,000 ng/L were measured within the Building 1160 plume core. The primary borings at Building 1194/95 were completed downgradient of the reported fire truck parking area, to the east/southeast of Building 1195. PFOS was detected in saturated soil at a maximum concentration of 66,000 ng/kg just below the water table (16.5 to 17.0 feet bgs) at soil boring PS-1. PFOA was not detected in soils at Building 1194/95. Shallow groundwater concentrations east of Building 1194/95 indicate PFOS concentrations of 7,200, 9,600, and 4,500 ng/L at borings PS-1, PS-2, and PS-3, respectively. Concentrations of PFOA in groundwater were 1 order of magnitude less, with corresponding concentrations of 130, 110, and 170 ng/L, respectively. Based on the concentration distribution, two comingled groundwater plumes were interpreted at Transects 1, 2, and 3, with concentrations of PFOS up to 10,000 ng/L likely attributed to the Building 1194/95 source area.

For the GAAF, the high-resolution permeability data and estimated K values obtained with the HPT and concentration data collected from VAP borings were evaluated using the three-dimensional (3-D) model Earth Volumetric Studio (EVS; C Tech Development Corporation, Las Vegas, Nevada) to facilitate mass flux evaluation. The three transects at the GAAF were modeled independently to provide a 3-D evaluation of mass flux and mass discharge along successive planes within the aquifer. This approach provided insight to mass movement, plume maturity, and plume morphology, allowing for future evaluation of remedy approach, location, design, and performance assessment. The nodal data from the mass flux model were summed to estimate the total mass discharge along each transect. The mass flux distribution is shown on Figure 9 (all three transects) and Figure 10 (Transect 1), below. A summary of mass discharge previously estimated for PFOS and PFOA is presented in Table 3, below.

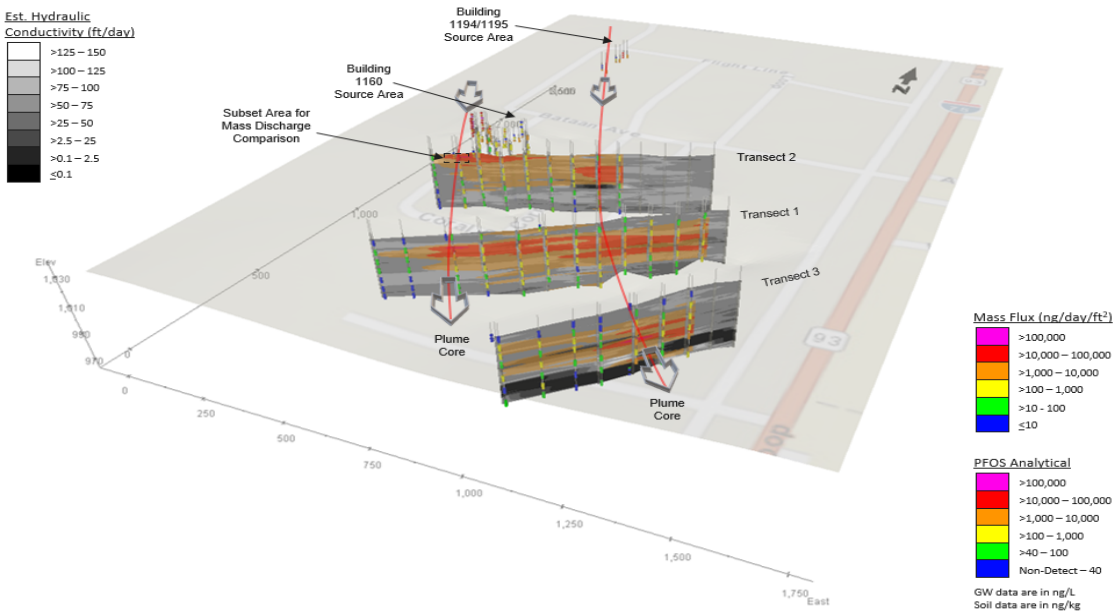

**Figure 9. Previous Estimated Hydraulic Conductivity Values and Estimated PFOS Mass Flux at Three Transects at GAAF Completed as Part of ESTCP Project ER19-5203 and Based on Data Collected in 2019**

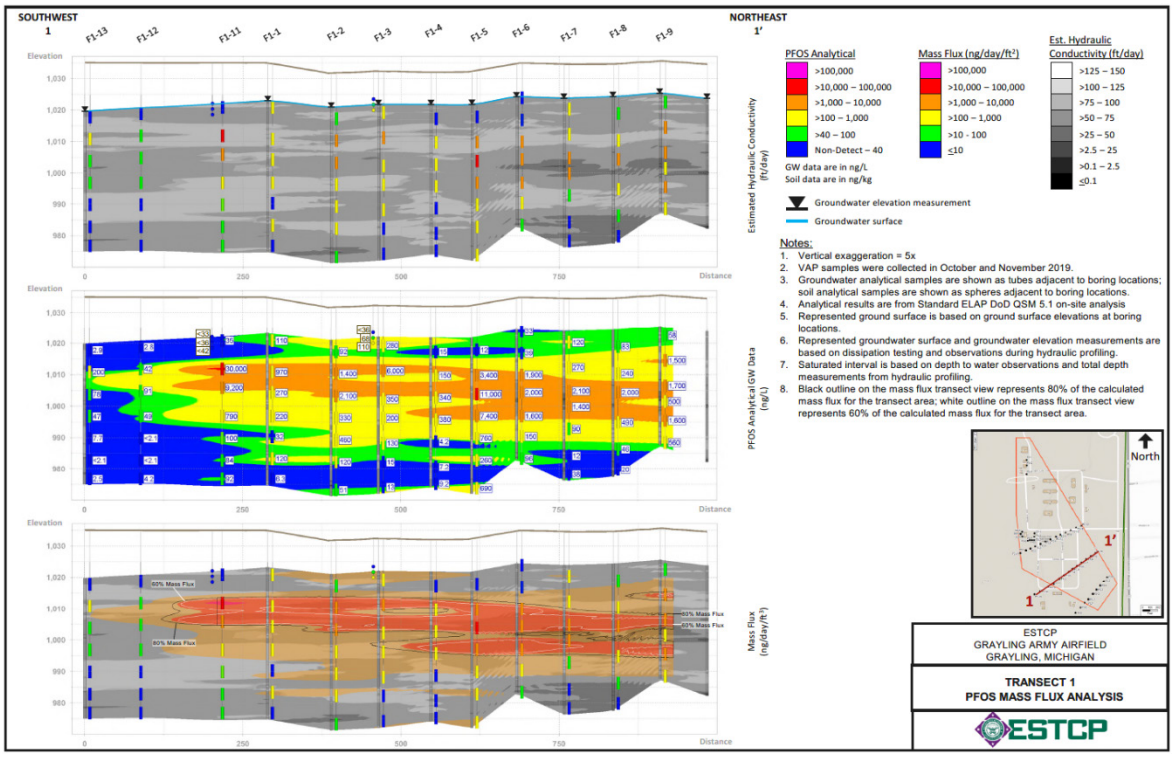

**Figure 10. Previous Estimated Hydraulic Conductivity Values and Estimated PFOS Mass Flux Transect 1 at GAAF Completed as Part of ESTCP Project ER19-5203 and Based on Data Collected in 2019.**

**Table 3. Summary of Previously Estimated PFOS and PFOA Mass Discharge Estimates as Part of ESTCP Project ER19-5203 and Based on Data Collected in 2019**

| | Hydraulic Gradient | Cross-Sectional Area | Groundwater Discharge for Cross-Sectional Area | PFOS Mass Discharge | PFOA Mass Discharge |
|---|---|---|---|---|---|
| | | square feet | gallons per minute | milligrams per day | milligrams per day |
| **Transect 2** | 0.005 | 28,312 | 52 | **122** | **6** |
| **Transect 1** | | 43,543 | 79 | **224** | **14** |
| **Transect 3** | | 25,938 | 37 | **62** | **10** |

The calculated PFOS mass discharge was greatest on Transect 1, which was also the longest transect and spans sections of both groundwater plumes (Table 3, above). The lowest PFOS mass discharge was along Transect 3, which is the farthest from the source areas, covers the smallest cross-sectional area, and does not intersect the Building 1160 plume core. Of note, although Transects 2 and 3 have similar cross-sectional areas, and Transect 2 intersected both plumes, the PFOA mass discharge was higher at Transect 1 located farther downgradient than Transect 2. The increasing concentrations of PFOA with distance may be due to the higher relative mobility of PFOA compared to PFOS. The PFOA distribution supports the conclusion of a mature plume with the highest concentrations shifted downgradient of a largely depleted source area (i.e., Building 1160). As noted above, this interpretation is also supported by the age of the source area (at least 30 years) and source sampling indicated 1 order of magnitude lower concentration of PFAS in groundwater/pore water than observed downgradient at Transects 1 and 2. For this project (ER20-5026), the VWSs was completed near Transect 2 because of its proximity to the Building 1160 source area, relatively high concentrations, and VWS length required to capture the plume core width.

# 5.0 TEST DESIGN

This section describes the baseline characterization efforts, VWS design and installation, and performance monitoring that were conducted during the demonstration to address the performance objectives described in Section 3.

## 5.1 CONCEPTUAL EXPERIMENTAL DESIGN

The overall goal of this project was to demonstrate and validate the VWS as a technology for reliable long-term monitoring of contaminant mass flux/discharge from contaminant source zones. The experimental design used to evaluate the performance objectives included six major tasks with several subtasks. The main tasks are listed below:

- Task 1: Site Selection
- Task 2: Methods Development
- Task 3: Pre-Design Data Collection
- Task 4: VWS Installations
- Task 5: Performance Monitoring
- Task 6: Reporting, Deliverables, and Technology Transition.

## 5.2 PRE-DESIGN DATA COLLECTION

At the GAAF, the prior transect-based approach (ESTCP project ER19-5203) applied the Geoprobe® HPT to assess vertical variability in K values (McCall and Christy 2020) combined with VAP groundwater sampling to assess variability in PFAS contaminant concentrations. This methodology was very successful and provided quantitative insights along the three transects investigated, showing significant variability in mass flux/discharge within the PFAS plume. Results are summarized in the Spring 2021 In Progress Report (IPR) for this project. Soil sampling was also conducted at source areas and a few locations along the transects focused on the capillary fringe and shallow water table zone to evaluate the potential PFAS mass storage within soils at the air-water interface.

The current ESTCP project (ER20-5026) was focused on one of the three existing vertical transects (Transect 2, located immediately downgradient of the source area; Figure 11) and includes the installation of two VWS installations at different depth intervals perpendicular to groundwater flow, and an additional installation forming a longsect parallel to the groundwater flow direction at a single depth interval intersecting Transect 2.

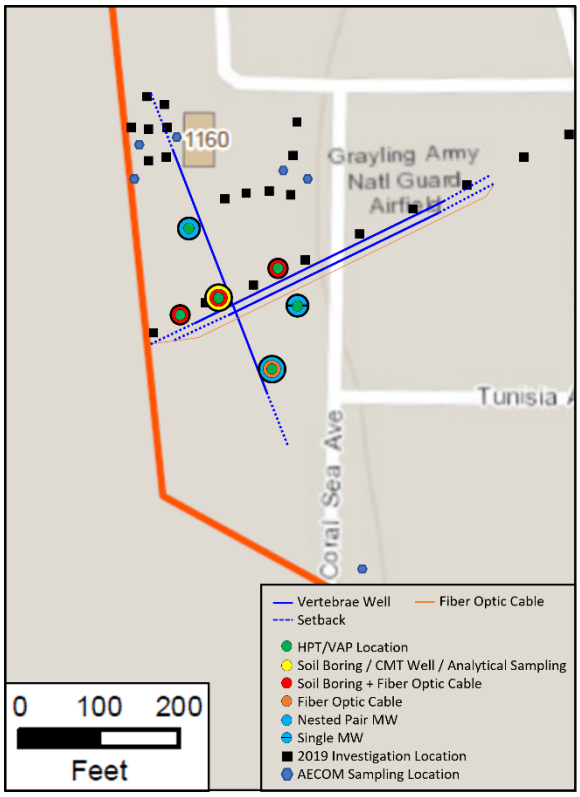

**Figure 11. Locations of the Vertebrae™ Wells and Additional Site Characterization Efforts**

The existing site characterization data were used as a basis for the locations of the VWS transects and screen sections. Furthermore, the robust mass flux/discharge estimates developed during the previous work represent a highly valuable and unique dataset that was used (and supplemented with the updated vertical transect data collected as part of this project) to evaluate mass flux/discharge values estimated with the VWS wells for the demonstration project.

Based on a detailed review of the available data and acknowledging recent advances in methodologies for site characterization with specific applicability to PFAS sites, and further considering project goals, additional vertical characterization activities were conducted. The additional site characterization efforts included additional HPT/VAP direct-push borings along the selected transect, as well as installation of conventional and multilevel wells for temporal groundwater sampling and hydraulic monitoring, which were also used for transducer deployments. The new conventional wells were positioned to provide insights on horizontal hydraulic gradients across the transect to be applied in groundwater flux/discharge estimates. Continuous cores were also collected to allow comparisons of K/groundwater flux assessed using other methods (e.g., HPT results and A-DTS) and for high-resolution sampling for PFAS concentrations at one targeted location, allowing comparison with depth-discrete groundwater sampling data conducted at a lower resolution than is possible via core sub-subsampling.

The additional characterization efforts provided insight into vertical variability, including temporal changes, and allowed improved temporal monitoring during this project period. In particular, the degree of temporal variability in the vertical dimension is of interest for application of VWSs, given these can only practically be deployed to monitor one or a few different depth zones.

Results from the additional data collection described throughout the remainder of this section were used to support the final design of the VWSs and the overall performance objectives assessment. The completed locations are shown on Figure 11, above, and the scope of work is presented in Table 4, below.

**Table 4. Summary of Pre-Design Scope of Work**

| Description | Number of Locations | Depth (feet) | Scope of Work/Data Provided |
|---|---|---|---|
| HPT borings | 6 | 40 | • Profiling of K |
| VAP borings | 5 | 40 | • Groundwater samples from five to six discrete intervals<br>• PFAS laboratory analysis<br>• Hydraulic conductivity estimates from pneumatic slug testing:<br>– Two locations with testing at four intervals<br>– One location with testing at five intervals |
| Vertical fiber optic cable | 4 | 40 DTS<br>50 total depth | • Continuous soil cores<br>• Hydraulic conductivity estimates from grain-size samples<br>• Darcy velocity from A-DTS thermal testing |
| Golden spike boring | 1 | 40 | • Continuous soil core<br>• Soil sample laboratory analysis (25 PFAS samples, five total oxidizable precursors (TOP) assay, five liquid chromatography quadrupole time of flight mass spectrometry [LC-QTOF])<br>• Hydraulic conductivity estimates from grain-size samples |
| Multilevel system (MLS) monitoring well | 1 | 40 feet (7 screens between 15 and 40 feet bgs) | • Continuous soil core (location of Golden spike boring)<br>• Groundwater samples for PFAS laboratory analysis<br>• Hydraulic head monitoring |
| Conventional monitoring wells | 5 (two clusters with two wells and one single well) | Two-well cluster: 20 feet and 30 feet<br>Single well: 20 feet | • Continuous soil cores<br>• Groundwater samples for PFAS laboratory analysis<br>• Hydraulic head monitoring (including pressure transducers in three of five wells)<br>• Hydraulic conductivity estimates from solid slug and pneumatic slug testing<br>• Darcy velocity from SWTT |

**Note:** DTS = distributed temperature sensing

### 5.2.1 Additional Hydraulic Profile Tool Borings and Vertical Aquifer Profile Sampling

Five new HPT/VAP profiles to 40 feet, with one additional HPT profile (without paired VAP) to 40 feet, were completed using the same methodologies applied in the prior investigations along the transect and longsect alignments (Figure 11, above) to provide additional vertical resolution of PFAS concentrations and mass flux/discharge for VWS placement, as well as evaluate potential temporal changes since the initial dataset was collected in 2019. Three locations filled high-value data gaps by splitting distance between previously completed HPT/VAP locations along the transect. Two locations filled high-value data gaps along the longsect (one upgradient and one downgradient of the transect).

VAP groundwater samples were collected from five to six discrete intervals per boring within a depth interval from approximately 15 to 40 feet using a Screen Point sampler with vertical sampling zones of 4 feet. Pneumatic slug tests to measure K were completed at four intervals at two HPT/VAP locations and at five intervals at one HPT/VAP location. Continuous cores were also collected at three locations. This provided additional information on lithology and soil samples for testing (e.g., grain size, thermal conductivity).

HPT borings were advanced using direct-push drilling techniques, in general accordance with procedures described in Arcadis' Technical Guidance Instruction (TGI) for Geoprobe HPT Investigations. The final data report from Cascade Technical Services, including HPT logs, is provided in Appendix B. The HPT provides a continuous profile of relative soil permeability at the centimeter scale (McCall and Christy 2020). The resulting profile was used to correlate hydrogeologic units across a site and guide selection of depth intervals for VAP groundwater sampling. The HPT tool is attached to the end of a drill string and enables a continuous metered injection of small volumes of water (typically between 200 to 300 milliliters per minute) during advancement of the probe. At the same time, the fluid backpressure due to injection into the formation, as well as the flow rate, are measured and logged at a high frequency. After correcting for atmospheric and hydrostatic pressure effects, the flow and pressure data are plotted as relative K by recognizing that K is proportional to flow divided by pressure (Q/P). The HPT also includes a dipole that logs the electrical conductivity of the soil to assist with correlating stratigraphy between HPT borings. Increasing clay content may correspond to increasing electrical conductivity. Empirical models can be applied to the datasets to provide an estimated hydraulic conductivity profile within limits at both the higher and lower end (McCall and Christy 2020). Other datasets providing K data including pneumatic slug testing and K estimated from grain size were used for comparison purposes, and potentially calibrating the estimated K from the HPT datasets.

VAP borings were advanced using direct-push drilling techniques, in general accordance with procedures described in Arcadis' TGI for VAP Sampling. VAP groundwater samples were collected from multiple discreet intervals using a 4-foot-long stainless steel screen point sampler with disposable tubing connected to a peristaltic pump. The process began by advancing a screen point sampler to the deepest interval and retracting the probe rods to expose the screen. The screened interval was developed by purging a minimum of 3 well volumes. PFAS-specific sampling considerations include avoiding PFAS-containing materials and cross-contamination potential. The groundwater samples were submitted for PFAS laboratory analysis and results are presented in Table 5. The laboratory analytical reports are provided in Appendix C.

Pneumatic slug testing was performed at select VAP groundwater sampling intervals, after the interval had been purged and sampled, to estimate K. Field testing procedures followed the Geoprobe Pneumatic Slug Test Kit Installation & Operation Instructions and Arcadis' TGI for Pneumatic Slug Testing. Pneumatic slug tests were conducted by sealing the well head and applying air pressure to depress the water level. As air pressure increased in the well, the water level fell until the water pressure and the air pressure return to equilibrium. After the water level was stable, air was released from the sealed well head by opening an air release valve. The water level recovery (i.e., rising head) typically produced very high-quality data with little interference. A pressure transducer was used to monitor and record the change of the water level in the well during the pneumatic slug test. The data were analyzed using Aqtesolv. K estimates determined by pneumatic slug testing are provided in Appendix D, along with the individual slug test solutions for each test.

**Notes:**

1**. Bold -** Result denotes detection

**Abbreviations:**

ft bgs - feet below ground surface
ID - Identification
ng/L - nanograms per liter
PFAS - per- and polyfluoroalkyl substances
TOP - total oxidizable precursor

**Qualifiers:**

B - Detected in the method blank
E - Quantitation of compound exceeded the calibration range
H - Out of holding time

J - Estimated value between the limit of quantitation and the method detection limit.

Q - Indicates a non-compliant QC Result (see Q flag application report: surrogate failure)

S - Indicates a non-compliant QC Result (see Q flag application report: MS/MSD failure)
U - Not detected at or above the limit of quantitation

**Notes:**

1**. Bold -** Result denotes detection

**Abbreviations:**

ft bgs - feet below ground surface
ID - Identification
ng/L - nanograms per liter
PFAS - per- and polyfluoroalkyl substances
TOP - total oxidizable precursor

**Qualifiers:**

B - Detected in the method blank
E - Quantitation of compound exceeded the calibration range
H - Out of holding time
J - Estimated value between the limit of quantitation and the method detection limit.
Q - Indicates a non-compliant QC Result (see Q flag application report: surrogate failure)
S - Indicates a non-compliant QC Result (see Q flag application report: MS/MSD failure)
U - Not detected at or above the limit of quantitation

### 5.2.2 Golden Spike Boring

One golden spike boring was completed using continuous core collection methodologies and a compact sonic drill rig (Boart Longyear LS-250) with a Lexan-lined split core barrel, which was advanced via sonic vibration only (no rotation) using the sonic 4 x 6 coring system with nominal 4-inch core barrel and 6-inch override casing. The core is contained within the clear Lexan liner, which is removed from the split core barrel at surface, providing less core disturbance than conventional sonic cores where the core is vibrated out of the core barrel into plastic sleeves at surface. The core barrel was over-rode with 6-inch sonic casing after each core run to maintain the borehole and for the subsequent MLS installation through the casing. At surface, the Lexan liner was placed in a cutting jig and split longitudinally using a skill saw to cut through the liner along the core axis at both sides of the core to expose the sediments, and the core was then split with scrapers for subsequent geological logging and subsample collection. Figure 12, below, shows the coring setup and process.

Soil boring logs are provided in Appendix E. This boring was installed at the location of highest expected PFAS concentrations and at the intersection of the transect and longsect VWS wells. It was also co-located with a vertical fiber optic boring and subsequent MLS installation in the same borehole. The cores were focused on an interval starting at a depth of 5 feet bgs, extending from the vadose zone across the capillary fringe and below the water table to the expected bottom of the primary plume and below the final depth of the deepest VWS to a total depth of 40 feet bgs.

The coring method selected in hindsight was not ideal for the coarser sediments at the GAAF with lack of much finer grained units, such that porewater retention, mobilization, and loss were issues that impacted the core sample results. However, alternative coring methods that would be more suitable (described below) were not available from the selected drilling contractor. Cores were collected in seven 5-foot runs over a 35-foot total vertical interval from 5 to 40 feet bgs. Figure 12, below, shows photos of the seven core runs collected and recovery is shown on Figure 13, below. Core recovery ranged from 32 to 100% (arithmetic average recovery of 67%) but with zero recovery on the first coring pass on three of the seven core runs, where core materials dropped out of the core barrel on the first pass. For these intervals the core barrel was advanced a second time through the outer (over-ride) casing to recover the lost materials, but these would have been highly disturbed. For all core runs, the core sediments were visually observed to be damp only; it is likely that much of the porewater drained from the cores during the retrieval to surface process, which would impact the subsequent core subsample results.

Alternative coring methods capable of providing greater recovery and porewater retention should be considered for any future efforts where it is desirable to use cores for detailed characterization of PFAS mass distribution. These could include consideration of the Aqualock piston sampler or cryogenic coring methods (Johnson et al. 2013; Kiaalhosseini et al. 2016; Trost et al. 2018; Kearney et al. 2024).[2]

High-resolution soil subsampling was completed at this boring (e.g., average 0.5-foot spacing, but with higher resolution targeted sampling around the capillary fringe and at low-permeability

[2] www.royaleijkelkamp.com/products/drilling-cpt/sonic-drilling/tooling/aqualock-piston-sampler/

interfaces) for PFAS porewater extraction and analyses. These employed the latest PFAS extraction methodologies including cationic PFAS extraction and analytical methods (Nickerson et al. 2020; Adamson et al. 2020) including the typical short list of approximately 24 targeted PFAS compounds, along with advanced analyses including TOP analyses and LC-QTOF analyses on selected samples. This high-resolution core sampling was intended to provide unique insights into the PFAS mass distribution, including at the capillary fringe and below the water table where not all of the mass may be mobile (e.g., sorbed mass fractions in lower permeability zones), at a resolution much higher than can be targeted with groundwater sampling. A total of 51 discrete-depth samples were collected in the field and selective analysis was employed to prioritize samples for analysis (Figure 14, below). The core samples ultimately analyzed included 27 PFAS samples, eight TOP assay samples, and five LC-QTOF samples for non-targeted PFAS analysis, plus quality assurance/quality control samples. Sample counts are discussed in Section 5.6).

Besides detailed subsampling of cores for contaminant analyses, split core samples were collected at high resolution (commensurate with observed lithologic variability) from 50 of the 51 sample depths into specimen jars. These samples were analyzed for grain-size distributions and subsequent K estimates based on grain size (Devlin 2015) for independent and comparative assessment of groundwater flux. An overview of the methods for the grain-size analyses and K estimates, along with the results, is provided in Appendix F. Continuous cores were also collected at two additional locations for paired monitoring wells with Geoprobe MC5 methods for core logging and collection of physical property samples only. The PFAS soil laboratory analytical results are presented in Tables 6 and 7.

**Notes:**

1. **Bold -** Result denotes detection

**Abbreviations:**

DOD ELAP - Department of Defense Environmental Laboratory Accreditation Program
ft bgs - feet below ground surface
ID - Identification
µg/kg - micrograms per kilogram
PFAS - per- and polyfluoroalkyl substances
TOP - total oxidizable precursor

**Qualifiers:**

J = Estimated value between the limit of quantitation and the method detection limit.

S = Indicates a non-compliant QC Result (see Q flag application report: MS/MSD failure)
U = Not detected at or above the limit of quantitation

**Notes:**

1. **Bold -** Result denotes detection

**Abbreviations:**

ft bgs - feet below ground surface
ID - Identification
µg/kg - micrograms per kilogram
PFAS - per- and polyfluoroalkyl substances

**Qualifiers:**
J - estimated value between the limit of quantitation and the method detection limit.
U - Not detected at or above the limit of quantitation.

### 5.2.3 Vertical Stand-Alone Integrated Fiber Optic and Heating Cables

The Morwick G360 Institute has developed an A-DTS method applicable to bedrock boreholes to quantify groundwater flow through fractures (Coleman et al. 2015; Maldaner et al. 2019; Munn et al. 2020). This method involves installing a composite fiber optic cable containing both optical fibers and heating wires in a borehole, temporarily sealing the borehole with a flexible liner, and heating the cable at a constant rate for an extended period (greater than 10 hours; Figure 15, below). The depth-discrete temperature is measured continuously along the full length of the borehole using a fiber optic cable (installed in the borehole) that is connected to an A-DTS at the surface. Modern DTS units can obtain high measurement, spatial, and temporal resolutions of up to +/- 0.01 degree Celsius (°C), 0.29 meter, and 2 seconds, respectively. The rate of temperature increase during heating is proportional to the bulk thermal conductivity of materials surrounding the cable at each depth. If no groundwater flow is present, this rate reflects the thermal conductivity of the saturated aquifer materials. If groundwater flow is present, the thermal conductivity is enhanced as the flow dissipates heat more efficiently, with the magnitude of the shift proportional to the groundwater flow rate (Maldaner et al. 2019). This allows depth-discrete groundwater flow rates through fractures in bedrock aquifers to be estimated using A-DTS tests.

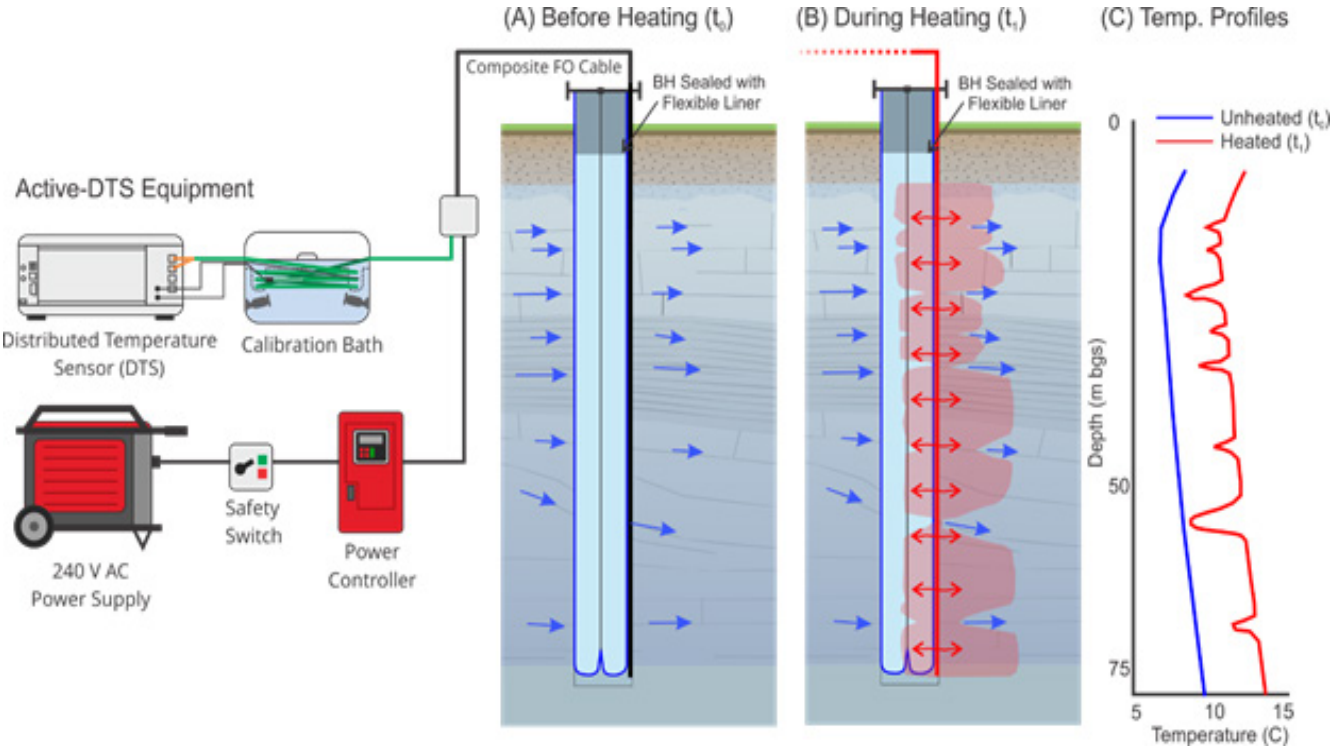

**Figure 15. Schematic of A-DTS**

*Schematic of A-DTS in a fractured rock borehole with the composite fiber optic and heating cable sealed behind a blank FLUTe™ liner. Active groundwater flow causes preferential cooling at those depths (modified from Maldaner et al. 2019).*

The University of Guelph has adapted the A-DTS methods developed for fractured bedrock and applied them to unconsolidated porous media building off experience from other researchers using DTS (Bakker et al. 2015; des Tombe et al. 2019). Initial heat and flow numerical modeling was completed to demonstrate proof of concept for unconsolidated media within the expected range of groundwater flux at GAAF. The A-DTS measurements provide another independent measurement of groundwater flux and its vertical variability, which was compared with other groundwater flux measurements from vertical characterization to identify biases in the different methods. A-DTS has also been used in unconsolidated aquifers to estimate groundwater flux. Direct-push field installations of fiber optic cables have been used in conjunction with hot water injections and active heating in sandy aquifers to quantify groundwater flux (Bakker et al. 2015; des Tombe et al. 2019). Controlled sand tank experiments have also demonstrated the ability of A-DTS tests to quantify groundwater flux using various analytical approaches (Bakx et al. 2019; Simon et al. 2020).

Installation of the composite fiber optic cable in the offset vertical deployments at the GAAF involved a similar approach to that presented by des Tombe et al. (2019), which uses custom drive-point knockout tip and assemblies that will remain in the ground once the drill rods have been removed (Figure 16, below). The knockout assembly included a stainless-steel drive point with the same dimensions as a standard Geoprobe tip, but custom machined to include a ¾-inch national pipe thread (NPT) and wrench grooves to enable attachment of a 7.5-inch (19 centimeter [cm]) extension pipe that houses the fiber optic cable termination (U-bend splice) and heating cable connection. The cable then passed through a smaller diameter protective sleeve and cable gland and was secured and sealed with epoxy. This provided a waterproof and robust cable termination that can withstand the rigors of installation.

The cables were installed in the subsurface using a Geoprobe direct-push drill rig. Once the desired depth was reached (50 feet bgs), the rods were removed, leaving the drive point and fiber optic cable in the subsurface. This sometimes required a slight tap with a metal rod inserted inside the rods to get the drive-point assembly to release form the rods. Each cable took approximately 1.5 to 2 hours to install using this approach. Once the rods were removed, the sediment was observed to collapse around the cable to approximately the water table depth, and then silica sand was added to fill the open hole above the water table to close to ground surface, and bentonite was added around the cable near surface. The collapse below the water table provides direct contact with the sediment, eliminating any thermal interference other than the cable materials. After the four cables were installed, the optical fibers and heating cables were connected at the surface using the same composite fiber optic cable to form a continuous loop. This allowed simultaneous heating and depth-discrete temperature monitoring along all four vertical installations, allowing efficient data collection. These fiber optic cable installations were at the same borehole locations as HPT/VAP and/or continuous soil core sampling. Two of the vertical fiber optic cable installations were co-located with previously completed HPT/VAP locations along the transect and one was installed at the nexus of the VWS transect and longsect. A fourth cable was installed further south along the longsect, paired with an HTP/VAP location and nested monitoring well pair.

Continuous cores were collected at all three locations along the transect (at two locations using Geoprobe MC5 methods and at the golden spike location using sonic coring methods as described above). All cores were logged in detail and subsampled for physical property analyses (e.g., grain size, permeameter tests, thermal conductivity tests). The golden spike soil cores were also subsampled for contaminant analyses as discussed above.

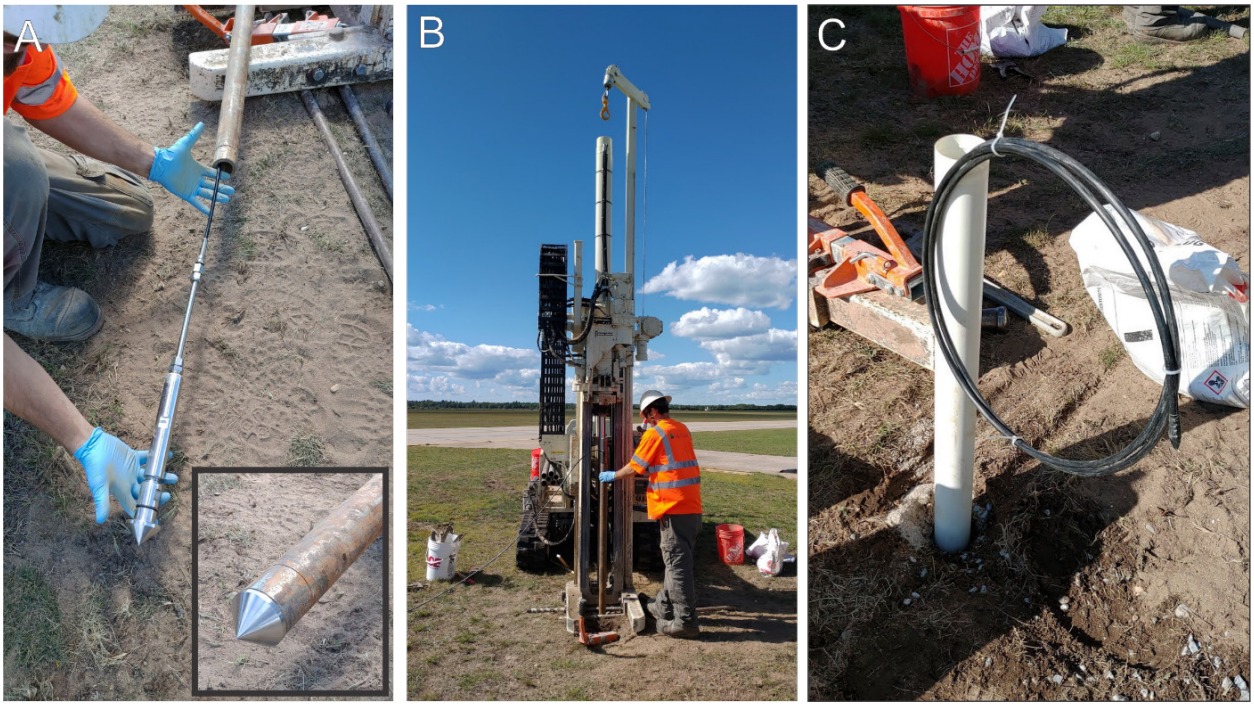

**Figure 16. Direct-Push Installation of Vertical Fiber Optic Cables for A-DTS Testing.**

*(A) Custom drive point/knockout tip with integrated U-bend housing installed into drill rods (inset showing assembly fully installed into rod), (B) Geoprobe drill rig pushing cable assembly to depth (50 feet bgs), (C) Surface cable at surface after installation with temporary PVC protective casing.*

### 5.2.4 High-Resolution Multilevel System

The installed MLS system at the golden spike location consisted of a seven-port CMT system (Einarson and Cherry 2002). Vertical screen positions were selected based on the soil boring and nearby HPT/VAP profiles, with two of the screen intervals coinciding with similar depths as the VWS screen intervals along the transect. The seven CMT ports were positioned within a depth range of 15.0 to 36.5 feet bgs, with vertical distance between ports ranging from 2.0 feet in the shallow interval near the water table to a maximum spacing between ports of 6.0 feet at depth. The system was constructed in the field following the CMT instruction manual by personnel experienced with construction of these systems.[3]

Figure 17, below, shows photos of the CMT multilevel construction and installation. The CMT system was installed to the target depth of 36.5 feet through the outer 6-inch-diameter sonic override casing on the same pass as collection of the continuous cores to 40 feet deep, as described in Section 5.2.2. Following installation in the casing, the casing was retracted leaving the MLS system downhole. Because the sediments at GAAF were expected to collapse and vertical gradients were expected to be negligible, seals were not placed between the screen intervals. Soil boring logs and monitoring well construction diagrams are provided in Appendix E.

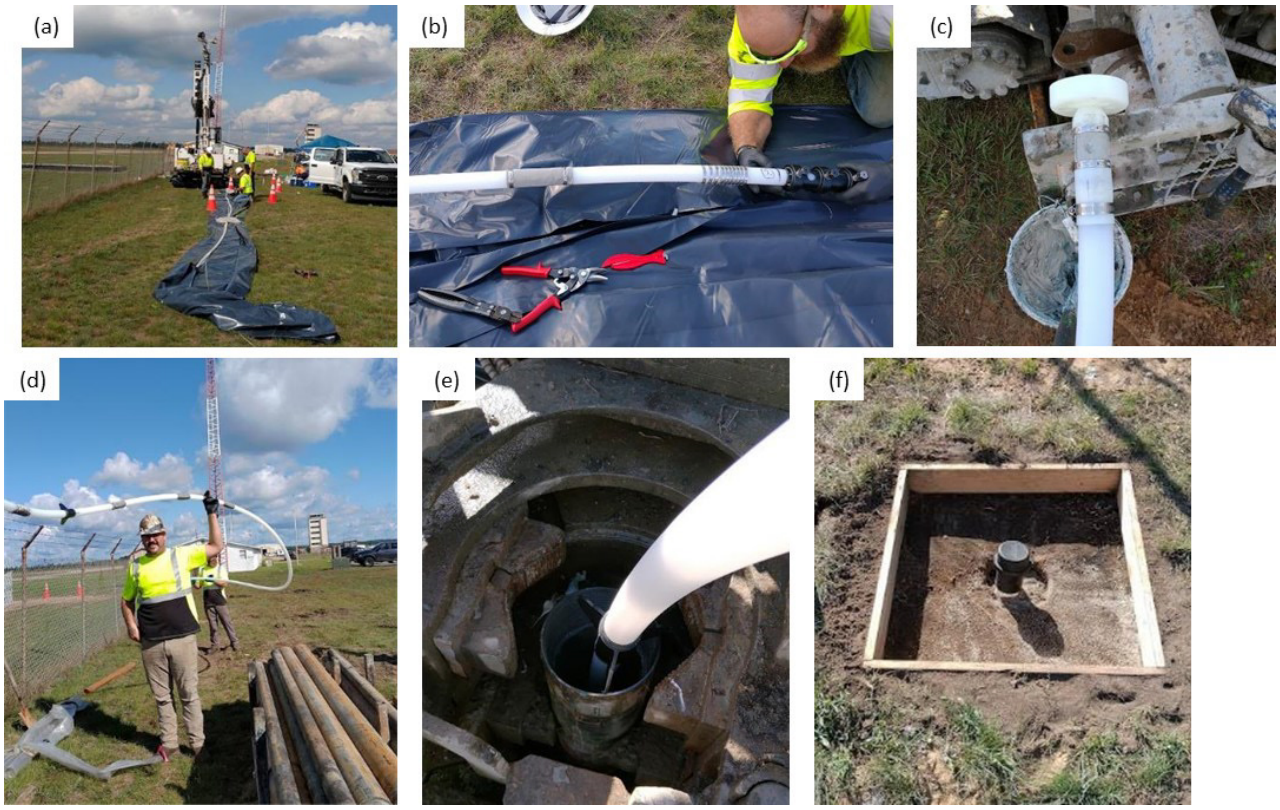

**Figure 17. Construction and Installation of Seven-Channel CMT Multilevel System**

*(a) Laying out CMT tubing on plastic sheeting to remove coil memory and marking port depths, (b) Lining up and cutting CMT ports and attaching stainless-steel screens over ports, (c) Bottommost Port 7 open to the middle channel and bottom anchor, (d) Transporting completed CMT for downhole installation, (e) Insert CMT multilevel down sonic casing, which is subsequently removed with vibration to promote collapse of sediments around the MLS, and (f) Completed CMT multilevel at surface with forms for pouring the final concrete pad.*

Following installation, the CMT ports were developed by purging using a peristaltic pump. Ports were purged until groundwater coming from each port was clear and field parameters monitored during purging efforts using a multiparameter probe verified that stabilization was achieved.

### 5.2.5 Conventional Monitoring Wells

A total of five additional monitoring wells were installed: two clustered monitoring well pairs and a single screen monitoring well. Soil boring logs and monitoring well construction diagrams are provided in Appendix E. The two new clustered (wells drilled separately, approximately 3 feet apart) monitoring well pairs were installed at different depths with short screen intervals (less than or equal to 5 feet) at two additional locations (one location upgradient and one downgradient) along the longsect coinciding with the groundwater flow direction and longsect VWS installation. One of the screens was co-located with a VWS port (i.e., spanning the same depth interval and positioned laterally at the mid-port position). The new monitoring wells were installed using HSA drilling techniques. The boreholes were continuously sampled, and the soil was described in general accordance with Arcadis' TGI for Soil Description, to depths of approximately 40 feet bgs.

After the soil cores were logged, the monitoring wells were installed in general accordance with procedures provided in Arcadis' TGI for monitoring well installation. The wells were constructed by installing 5-foot lengths of manufactured 2-inch-diameter, 10-slot (0.01-inch), rigid Schedule 40 PVC screen with a bottom cap. The actual screen intervals were determined based on conditions encountered in the field. Riser pipe consisting of 2-inch-diameter, rigid Schedule 40 PVC pipe extends from the top of the screen to ground surface and is coupled to the screen using threaded joints. The annulus around the screen was filter-packed with bagged silica sand with an appropriate grain size for the formation from the base of the borehole to approximately 2 feet above the top of the well screen. The annulus above the sandpack to the ground surface was sealed with bentonite.

Installed monitoring wells were developed to clear them of fine-grained sediment to enhance the hydraulic connection between the well and the surrounding geologic formation. Development was accomplished by evacuating well water by pumping. During well development, the pump was moved up and down the screened interval until the well yielded relatively clear water.

### 5.2.6 Pre-Design Investigation-Derived Waste Management

Investigation-derived waste (IDW) was generated during the pre-design phase of this project. Soils removed during drilling were surface spread on site; groundwater purged during well development and sampling as well as water used for decontamination purposes was also surface spread on site.

## 5.3 TREATABILITY OR LABORATORY STUDY RESULTS

Well material compatibility for sampling PFAS compounds was completed for this project by EN Rx. The laboratory study looked at several possibilities for leaching PFAS compounds and thus increasing PFAS compounds in the groundwater in addition to adsorption effects that could produce decreases in groundwater samples collected from the well screens. The two main findings are summarized below, and the summary report provided by EN Rx is provided in Appendix G:

- Only one PFAS compound (PFOA) was reported at a trace concentration (0.97 nanogram per liter [ng/L]) in a simple water rinsate sample collected from rinsing the geotextile fabric used for the construction of well screens. This concentration is below the MCL of 4.0 ng/L for PFOA. It is concluded the VWS materials will not cause leaching of PFAS compounds in applicable concentrations at most sites. However, a methanol wash procedure can be performed to ensure the VWS materials are PFAS free.
- PFAS compounds were found on the geotextile screen material and traces were found on tie wraps used to construct the VWS installed at GAAF (Table 8). Laboratory analytical results indicated the presence of 6:2-fluorotelomersulfonic acid (6:2-FTS), 4:2-fluorotelomersulfonic acid, perflouroheptanesulfonic acid, perfluorohexanoic acid, and perfluoropentanoic acid. Primarily, the main exceedance of the laboratory detection limit was centered around 6:2-FTS at 2,000 ng/g, which was several magnitudes greater than the other constituents detected (reported at trace concentrations of 3.9, 0.18, 0.33, and 0.20 ng/g, respectively), when sampling the geotextile fabric. The laboratory methods used methanol extraction to dissolve these compounds from the samples submitted. The other construction materials for the GAAF (risers and outer sleeve) did not report PFAS compounds. As a note, 6:2 FTS was also detected at 1,600 ng/g in the nylon pull tape typically used for well system construction; however, this component was removed and replaced by the tracer wire described in Section 5.4.1 for the purposes of well locating.

**Table 8. PFAS Laboratory Testing of VWS Well Materials**

| VWS Well Material Component | 6:2-FTS Initial Sampling Results | 6:2-FTS Post Pre-Cleaning Results |
|---|---|---|
| Sleeve-HDPE 3 inches | ND | ND |
| Tie-nylon wrap | 73 ng/g | ND |
| Geotextile screen wrap sock | 2,000 ng/g | ND |
| Riser-HDPE tubing ½ inch | ND | ND |
| Well screen - polyethylene proprietary design | ND | ND |

**Notes:** HDPE = high-density polyethylene
ND = nondetect

The data indicate that 6:2-FTS would not have provided any sampling interference under normal circumstances for groundwater investigation. However, all geotextile fabric used for system construction was washed using methanol and resampled to ensure no 6:2-FTS was present on the geotextile prior to installation of the VWS at the GAAF.

A minor finding of the summary report provided by EN Rx (Appendix G) was that three PFAS compounds (perflourooctanesulfonamide [PFOSA], perfluorotridecanoic acid [PFTrDA], and perfluorotetradecanoic acid [PFTeDA]), not present at the site, can adhere to the geotextile and could produce biases. However, this result was after soaking in a spike solution with very high concentrations of 1,000 ug/L for individual PFAS compounds. In addition, these are not typical primary compounds found at AFFF-impacted sites. Therefore, adhesion/adsorption biases are not practical to consider as interference when using VWS.

## 5.4 DESIGN AND LAYOUT OF TECHNOLOGY COMPONENTS

This section describes the VWS design and implementation. VWSs are premanufactured and typically no adjustments are completed in the field at the time of installation. For this reason, proper design is critical for field installation and successful well installation outcomes. This project included the installation of three VWS installations using HDD methods. Two VWSs are at different depth intervals perpendicular to groundwater flow (shallow and deep transects) and the third VWS is parallel to the groundwater flow direction at a single depth interval (longsect). In addition, a fourth boring was completed using HDD methods for installation of a stand-alone fiber optic cable for A-DTS testing. The stand-alone fiber optic cable was offset from and installed at approximately the same depth as the shallow transect VWS. As-built figures are provided in Appendix H, showing the profile and plan view layouts of the VWSs.

### 5.4.1 VWS Design Components

VWS construction is custom and can vary greatly depending on the usage. The following parameters are tailored to the specific use: riser diameter, well screen diameter, well screen slot sizes, well screen length, and spacing between well screens. Also, part of the design is the installation sleeve size (diameter), which can be adjusted to accommodate more well screens or other devices and can be altered for longer bores or more difficult lithology to accommodate higher frictions via higher tensile strength sleeves.

Typical design summary sheets with the current project design information are presented in Tables 6 and 7, below.

**Table 9. Overall VWS Design Summary**

| Well Systems | Segment (screen) Lengths | Segments | Segment Spacing (Average) |
|---|---|---|---|
| Three systems | 10 feet | Eight per system/24 total for all three systems | 35 feet |
| **Total Length (all systems)** | **Depth** | **Riser Size** | **Well Sleeve** |
| 1,390 feet | varies 20 to 30 feet | 0.75-inch HDPE | Four-inch 13.5 SDR HDPE |

**Note:** SDR = standard dimensional ratio

**Table 10. Individual VWS Summary**

| System Specs | Screen and Riser Specs | Spacing and Coverage | Other Details |
|---|---|---|---|
| Shallow transect - 500 feet with 4-inch sleeve | Eight – 10 feet long x 1-inch screens<br>Eight – 0.75-inch HDPE risers<br>Eight – 0.5-inch HDPE grout lines | 35 feet spaces for approximately 325 feet | 20 feet deep with exit<br>Full-length tracer and first well length tracer<br>One fiber optic cable full length |
| Deep transect - 501 feet with 4-inch sleeve | Eight – 10 feet long x 1-inch screens<br>Eight – 0.75-inch HDPE risers<br>Eight – 0.5-inch HDPE grout lines | 35 feet spaces for approximately 325 feet | 30 feet deep with exit |
| Longsect - 500 feet with 4-inch sleeve | Eight – 10 feet long x 1-inch screens<br>Eight – 0.75-inch HDPE risers<br>Eight – 0.5-inch HDPE grout lines | 35 feet spaces for approximately 325 feet | 20 feet deep with exit |
| Stand-alone fiber optic cable - 475 feet with two 0.75-inch sleeves (one for fiber optic cable and one for borehole development) | N/A | N/A | 20 feet deep with exit<br>1 fiber optic cable full length |

**Note:** N/A = Not applicable

The following VWS components are described further throughout the remainder of this section:

- Screens
- Risers
- A-DTS fiber optic cable
- Tracer wire
- Grout lines
- Protective sleeve.

### *5.4.1.1 VWS screens*

The first part of the design is screen selection. The VWSs generally consist of a proprietary well screen that is flexible to provide ease of installation and maximize contact with the subsurface. Typically, 1-inch nominal well screens are adequate for the flow and dimension requirements for sampling and most treatment technologies. Larger sizes are available for alternate uses. For this project, 1-inch nominal was appropriate. The well screen slot size is only changed for injection of slurries or when silts may hinder the use of the well. The application herein does not require a change from the typical geotextile sleeved screen. The well screen is wrapped in a Carriff® well sock. This is an 88-denier polyester fabric used in the industry for more than 30 years, which provides a pore size that is effective at passing small silts and remaining clear in various formations. Other wraps are available for use (e.g., stainless-steel mesh); however, these were not required based on the design for this project.

To accommodate a moderate amount of data density, eight well screens were used per well system. To cover the selected portion of the plume, well screens were 10 feet in length and spaced 35 feet apart. This spacing and construction dictate the rest of the dimensions to the surface.

### *5.4.1.2 VWS well risers*

A typical cross-section diagram with the approximate build structure is shown on Figure 18, below. The well screens are attached to well risers to extend to the surface (not individually shown due to scale). These risers are HDPE and are continuous in nature (no couplers, joints, or welds are typically used). The size and thickness of the HDPE is dependent on the flow and pressures the project requires. Well riser diameters range from 0.375-inch outer diameter (OD) to 1.5-inch OD. For sampling, usually 0.5-inch OD is suitable. In this case, to add an insert for tracer injection, a larger size was needed. A riser consisting of 0.75-inch OD tubing with wall thickness of 0.0625-inch was used.

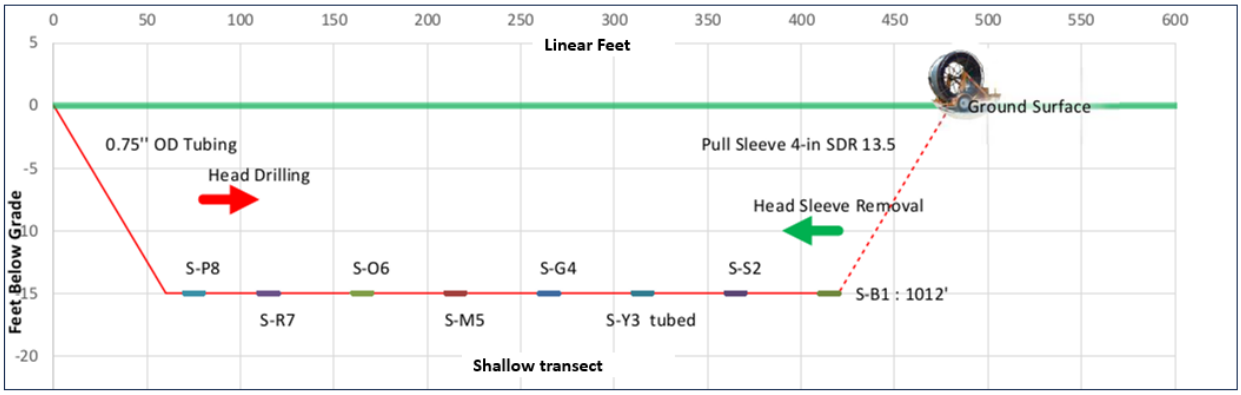

**Figure 18. Shallow Transect VWS Cross-Section Diagram**

### *5.4.1.3 A-DTS Fiber Optic Cable*

A fiber optic cable was co-installed with the shallow VWS transect system to allow both groundwater chemistry and flux to be measured from a single installation. However, certain complexities exist with this approach, such as control of placement of the composite cable within the system and variations in materials surrounding the cable (e.g., VWS tubing), which variably affect the heat transfer from the cable, increasing the uncertainty to quantify groundwater flux (Figure 19, below).

To assess the degree of uncertainty and to maximize the likelihood of quantifying flux, two other cable deployments were completed for this project: a stand-alone cable installation in a parallel horizontal borehole adjacent to the VWS and four direct-push vertical stand-alone installations along a transect perpendicular to the flow direction paired with other vertical characterization profiles (e.g., Geoprobe HPT/VAP sampling), sediment cores, and an MLS for temporal monitoring and sampling (see Section 5.2). These additional stand-alone cable installations remove the complications of the cable placement with the VWS and variable thermal influence of well materials and provide a basis of comparison for the results from the VWS installation. Similar direct-push deployments have shown success at quantifying groundwater flux in sandy aquifers (Bakker et al. 2015; des Tombe et al. 2019). An additional application of the A-DTS method includes assessment of the grout seals between well screens in the VWS, as discussed further in the performance evaluation section for Qualitative Performance Objective #2.

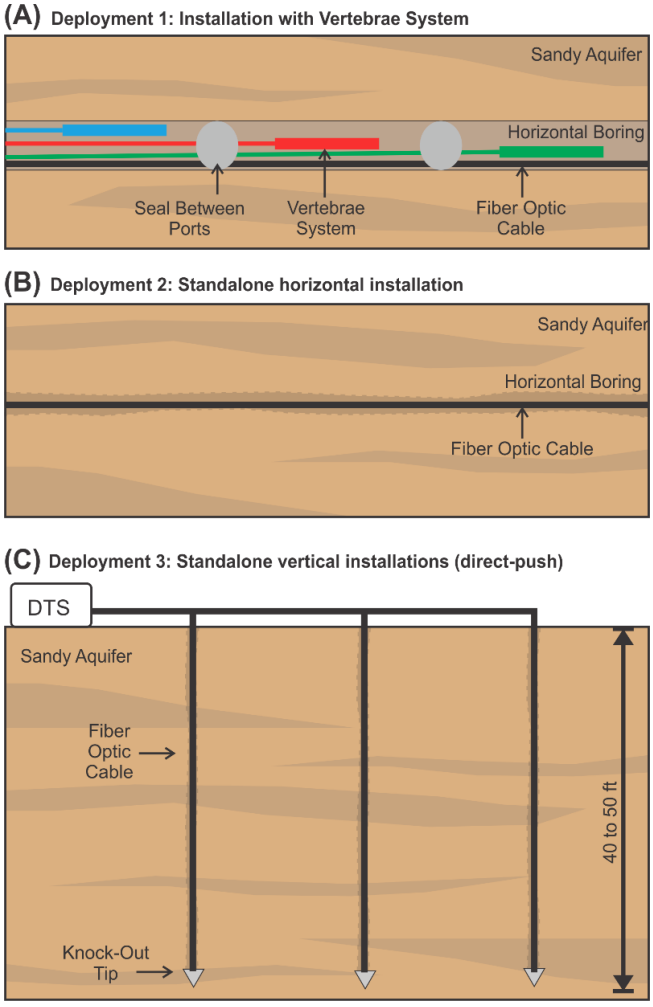

**Figure 19. Fiber Optic Cable Installations**

*Three different fiber optic cable installations were completed: (A) Cable installed with the VWS in the same hole, (B) Cable installed in a separate horizontal borehole, and (C) A series of cables installed in stand-alone vertical holes using direct-push methods. These vertical cables are connected at the surface to allow simultaneous temperature monitoring in all boreholes. In all three deployments, it was assumed the sediment would collapse providing direct contact between the sediment and cable.*

For the horizontal installation with the shallow VWS transect system, the fiber optic cable was added to the well assembly as it was manufactured. Both ends of the fiber optic cable are accessible at the surface and connectors and cable terminations were completed at the surface after the cables were deployed. For the stand-alone horizontal fiber optic cable installation, the cable required a semi-rigid HDPE tubing to aid installation of the cable through the boring; this tubing was removed once the cable was in place. The cable ends were completed at the surface in the same manner as the cable installed with the shallow VWS transect system.

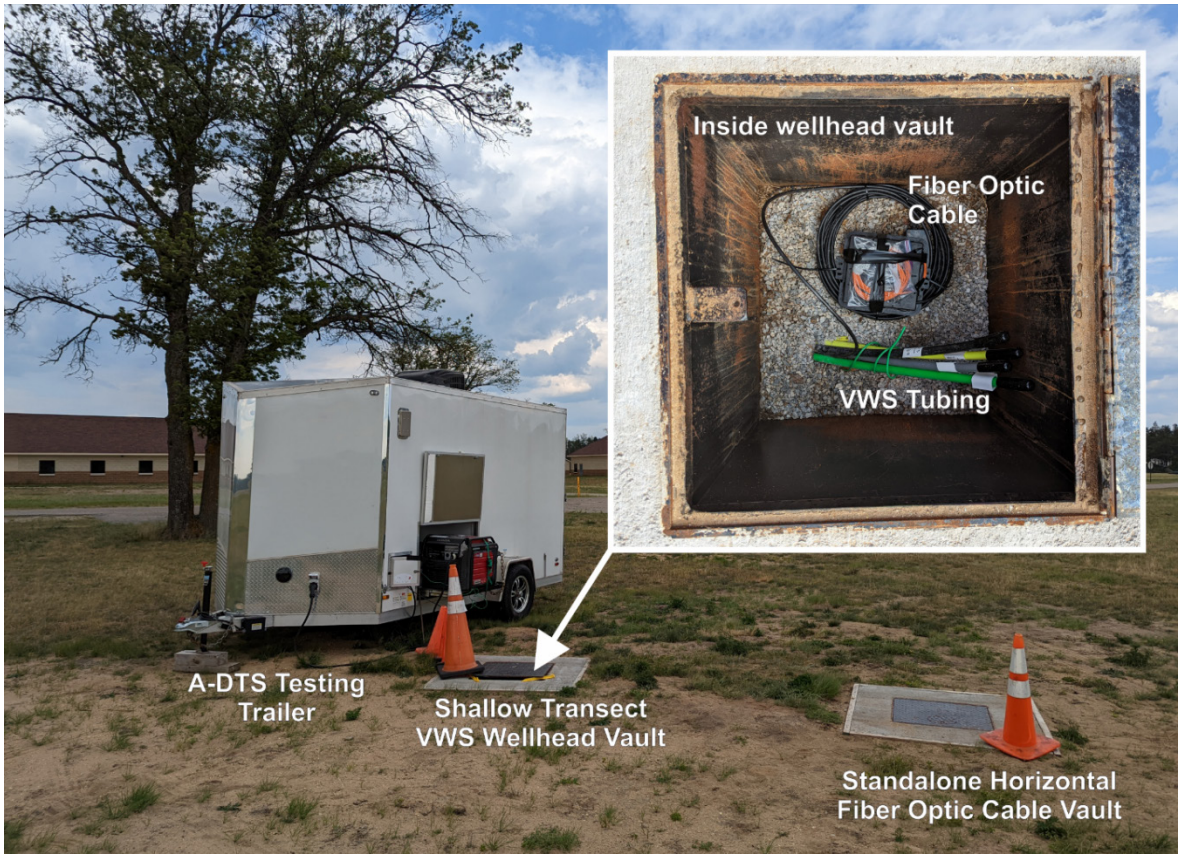

**Figure 20. Field Photos of Horizontal Fiber Optic Cable Installations for A-DTS Testing**

#### *5.4.1.4 Tracer Wire*

The well system is typically built with a polyester pull tape, often called mule tape. The pull tape has foot markings to allow easy build and field measurement to locate the well positions. The well screens are attached to the pull tape during manufacturing. For this project, the pull tape was replaced with a tracer wire as an upgrade to provide additional locating capability and additional assurance that the well materials are PFAS-free.

A tracer wire was included with the VWSs to provide post-installation locating capability. A high-strength copper clad steel tracer wire (Pro-Trace HDD-CCS PE45) was attached to the outside of each VWS from entrance to exit. The tracer wire is visible on Figure 20, above, inside the wellhead vault (thin green wire wrapped around the VWS tubing). The tracer wires can be used to locate the VWSs using inductive line tracing methods. A frequency can be applied by a transmitter to the horizontal well tracing wire, which permits well location using a receiver.

This will allow the locations to be marked prior to future subsurface activities such as drilling or excavation, to avoid damage to the VWSs. In addition, the tracer wires were used to verify accurate and reliable placement of the VWSs in the subsurface, which is one of the quantitative performance objectives.

Inclusion of the Pro-Trace tracer wire is also advantageous because it has length markings; therefore, a separate measuring tape is not necessary. Previous VWS installations included a nylon pull tape for measuring the well systems. As discussed in Section 5.3, 6:2-FTS was initially detected in the measuring tape sample. The use of the Pro-Trace tracer wire instead of the nylon measuring tape provided additional assurance the well materials were PFAS-free.

#### *5.4.1.5 Grout Lines*

Grout lines were built into the VWSs to allow easy tremie-style grouting during installation. These are located per the design at the intended spaced locations, including between each screen and at each end of the VWS. Grout lines generally consist of 0.5-inch OD HDPE pipe. Additional HDPE lines could be incorporated into the VWS design for additional purposes if desired. For example, if a fiber optic cable needed to be inserted after installation (but before grouting or development), it could be threaded into the additional line and then the line could be removed, leaving the fiber optic safely in place.

#### *5.4.1.6 Protective Sleeve*

The sleeve is the outer protective element of the well build. It aides in the build process and protects the well system when spooled and shipped; it also protects the well system during the installation process. Well sleeves are generally typical HDD conduits specified as 13.5 SDR HDPE pipe. EN Rx uses 3-, 4-, 5-, and 6-inch sleeves for construction. The larger sizes have more tensile strength and allow more internal well structures to be used but also require larger drill bits sizes and drill rig sizes to be installed. Larger sleeves also take up more room when shipping. For this project 4-inch HDPE sleeves were used for the three VWSs.

### 5.4.2 Bore Path Design

Drilling was performed using standard HDD, which is a mud rotary drilling method. The wells are double-ended, meaning that a pilot bore was directionally drilled starting at an entry pit and ending at an exit pit. Drilling commenced at the entry pit, proceeded at an angle to the target depth, continued horizontally, and then ascended to the surface at the exit pit. The pilot bore was then reamed to final diameter, and the well materials (or fiber optic cable) were pulled back from the exit end.

The VWS and other features must be placed at locations and depths suitable for the data and goals to be achieved. To ensure this is achieved, a detailed bore path design was completed to specify target depths and distances. Vermeer® Projects (software package) was used to design the bore path. This program accounts for the drilling capabilities, which include initial angles of advancement, rod flex, exit angles, and total distance. Figure 21, below, is a screen shot from this program representing the final bore path design. Once the program output was completed, the target locations and rod-by-rod specifications were downloaded into the drilling console for use by the drilling team.

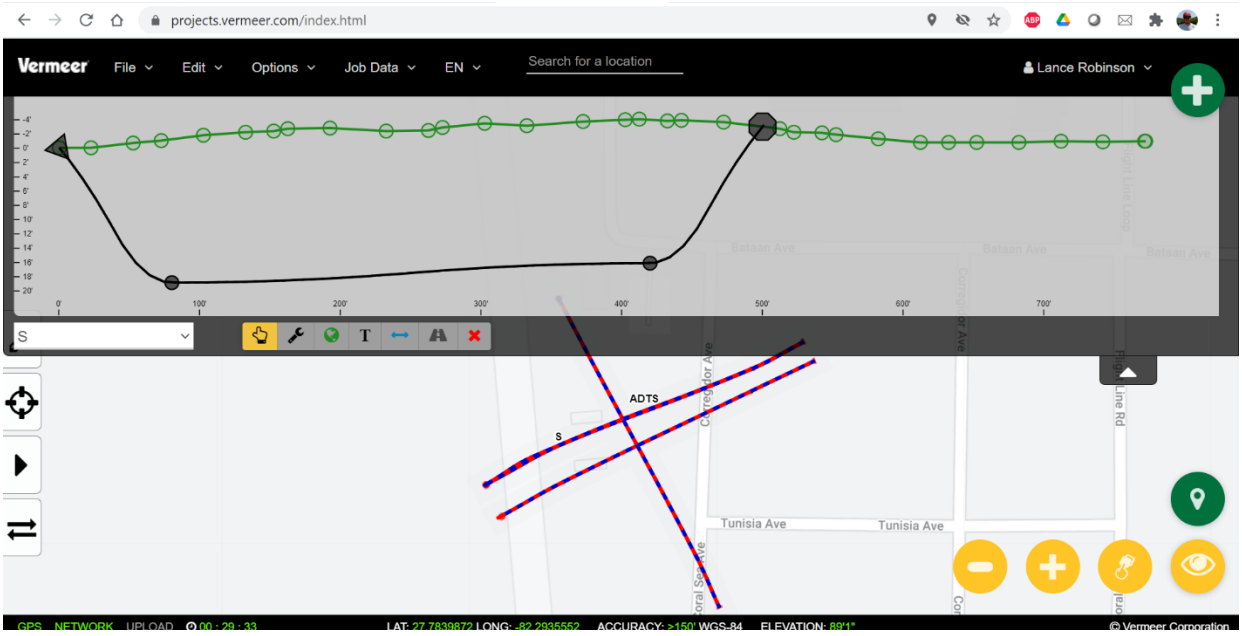

**Figure 21. Bore Path Design Diagram**

### 5.4.3 Drilling and Reaming Operations

Prior to drilling, points along each bore were surveyed and marked with wooden stakes. During drilling, the position of the drill bit was located every 10 feet (when a new rod was added to the drill string). A flag was used to mark the actual position of the bore, to allow comparison between horizontal and vertical position of the proposed and actual points.

Batches of bentonite-based drilling fluid were mixed before and during drilling as needed. The drilling fluid mixture for the project consisted of approximately three 50-pound bags of TRU-Bore® and 32 oz of soda ash to buffer/adjust the pH per 500 gallons of water. This mixture was used for the installation of the stand-alone fiber optic cable and for the first 80 feet of the shallow transect. During drilling of the shallow transect, fluid circulation was lost from 50 to 80 feet into the bore (total of 300 gallons of drilling fluid mixture). The loss of fluid flow was attributed to a change in lithology (apparent small cobble was encountered). The fluid mixture formulation was then adjusted to include 2 pounds of Xanthan gum per 500 gallons of drilling fluid mixture. This mixture was used to complete the shallow transect, deep transect, and longsect. The following is the total drilling fluid used for the completion of each bore:

- Stand-alone fiber optic cable: 3,000 gallons
- Shallow transect: 5,400 gallons
- Deep transect: 5,050 gallons
- Longsect: 5,100 gallons.

For each bore, the drill string entered the ground in the previously excavated entry pit. Drilling was accomplished by affixing the downhole drill head assembly to a rig-mounted drill rod, then pushing the assembly into the ground, alternately rotating and pushing without rotation to follow the desired bore path. The drill head assembly used a 5.5-inch, paddle-style drill bit suitable for sandy material for piloting and reaming a 6-inch bore. As the drilling proceeded, additional rods

were added to the drill string autonomously from the rod rack. While drilling, the driller and locating technician worked in coordination to steer the downhole assembly along the design azimuth and bore path, rotating and pushing as typical for HDD technology.

A walkover locating system was used to track the drill head during pilot bore drilling. For this project a DCI F5+ Falcon® locator was used, which includes state-of-the-art range and radio frequencies as well as drill head pressure sensors. The technology uses a sonde housed behind the drill head, which transmits a wireless radio signal (radiofrequency [RF]). A handheld receiver is then used at the surface to determine location, depth, and orientation of the drill head. This information is communicated to the driller via a rig display so the trajectory of the pilot bore can be continuously adjusted as needed to maintain the desired bore path. The walkover locating system requires surface access along the bore path and the specified equipment provided accuracy measurement within 3% of borehole depth, according to the manufacturer. The maximum depth of walkover locating technology is typically 80 feet, although newer higher end tools give capabilities up to 200 feet in some settings. Walkover locating was suitable for this project due to a maximum depth of the VWS installations being 30 feet, no obstructions at the surface, and no electromagnetic interference encountered.

### 5.4.4 VWS Installations

VWS installation is unique compared to other horizontal well installations. Generally, the well systems are built inside a sleeve (conduit as typical for HDD utility installation practices) and then spooled for shipment to the project site. The sleeve is pulled into the ground and has a high tensile strength, allowing for installation. This allows the internal components of the well system to be more fragile and for larger and latitudinal openings on the well screens. Once the well system is in the correct location for the project, the sleeve is removed, allowing the natural formation to collapse around it. This method offers three major additional benefits for well installation: mud removal via physical displacement of the drilling materials, more complete borehole wall collapse and breakdown of the bore skin, and protection of the well materials from occlusions and damage due to physical movement through the bore. These benefits offer a superior installation to traditional horizontal well installation as evidenced by quick and clear well development.

VWS installation commenced after the bore was properly drilled and the drill bit exited the ground on the terminal end of the bore. Based on drilling conditions and at the driller's discretion, a separate reaming pass to enlarge the borehole to 8 inches was completed prior to pullback of the VWS shallow transect and the longsect well materials. At the deep transect, a separate back reaming pass was not completed prior to pullback of well materials. Once the borehole was ready, the well system was attached to the paddle bit or back-reamer using a swivel and conduit head puller (a device built to expand inside a conduit to grip it internally so it can be pulled into the ground). Once attached properly, the drill rig operator back-reamed or retrieved the drill rod set, rod by rod, transgressing back through the bore to the entrance. Once the sleeve was completely inside the bore, the pull head was removed, and the well system was detached from any internal fixations. After the sleeve was filled with thinning agent as the first step in well development (see Section 5.4.5), the well system was then anchored so that it would be held in final position while the sleeve was removed. The sleeve was pulled from either the entry or exit location, depending on site logistics and the driller's preference. Once the sleeve was out of the ground, the well system was no longer able to be moved.

### 5.4.5 Well Development

#### *5.4.5.1 Initial Chemical Treatment*

As noted in the previous section, well development started with the introduction of a highly concentrated thinning agent (THINZ-IT®), mixed with fresh water, to induce breakdown of the viscosity of the drilling fluid and wall cake along the borehole. A 5-gallon container of THINZ-IT mixed with 300 gallons of fresh water was pumped into the end each carrier sleeve until full, prior to removal of the sleeves.

The stand-alone fiber optic cable bore consisted of two 0.75-inch conduits (one carrier conduit for housing the fiber optic cable and one for application of the THINZ-IT mixture as it was withdrawn from the bore). No additional borehole/well development was conducted at the stand-alone fiber optic cable location. Additional VWS well development activities conducted after removal of each carrier conduit are summarized below.

#### *5.4.5.2 Additional Chemical Treatment and Mixing*

The following activities were performed after removal of the sleeves:

- Five gallons of THINZ-IT mixed with 300 gallons of fresh water were introduced to the four well segments at the western end (shallow and deep transects) or northern end (longsect) of the well system, using a four-channel manifold.
- The four western or northern well segments were agitated with air for approximately 25 minutes using a 185 cubic foot per minute (CFM) air compressor.
- Five gallons of THINZ-IT mixed with 300 gallons of fresh water were introduced to the four well segments at the eastern end (shallow and deep transects) or southern end (longsect) of the well system, using a four-channel manifold.
- The four eastern or southern well segments were air agitated for approximately 25 minutes using a 185 CFM air compressor.

#### *5.4.5.3 Initial Pumping*

Once the appropriate residence time was allowed for the chemical solution to break the viscosity of the drilling fluid, a vacuum trailer capable of providing up to 20 inches of mercury was used to extract fluid from the well segments. Fluid was extracted first from one end of the well system then from the other end, using the same four-channel manifold:

- Shallow transect:
  - The western well segments yielded approximately 60 gallons in 30 minutes of pumping. The black well segment produced very little water.
  - The eastern well segments yielded approximately 60 gallons in 30 minutes of pumping. The red and purple segments produced very little water.
- Deep transect:
  - The western well segments yielded approximately 50 gallons in 30 minutes of pumping. The blue, silver, and yellow well segments produced very little water.

  - The eastern well segments yielded approximately 50 gallons in 30 minutes of pumping. The red and purple well segments produced very little water.
- Longsect:
  - The northern well segments yielded approximately 110 gallons in 1 hour of pumping. The black and silver segments produced very little water after approximately 15 minutes.
  - The southern well segments yielded approximately 75 gallons in 30 minutes of pumping. The red and baby blue segments stopped producing water after approximately 20 minutes.

#### *5.4.5.4 Final Chemical Treatment*

The low-yielding well segments listed above are atypical for the lithology. Therefore, it was determined that the xanthan gum added to the drill mud mixture needed additional breakdown/ development using an acid or an enzyme additive. Acid (muriatic) was readily available and was chosen for additional breakdown (thinning).

It should be noted that xanthan gum is rarely needed for installations unless cobble is present or other atypical conditions. Therefore, development of the well system does not typically include chemical treatment and the additional development that follows.

Initially, a mixture of 2 gallons of muriatic acid and 8 gallons of water for a total volume of 10 gallons was injected into the four eastern deep transect well segments. The mixture was allowed to set for approximately 2 hours. Minimal affect was noted. The concentration of the acid solution was then increased to 2 gallons of muriatic acid and 3 gallons of water for a total of 5 gallons.

Five gallons of this mixture were then injected into each of the 24 independent well segments contained in the shallow transect, deep transect, and longsect, and allowed to set for 24 hours.

#### *5.4.5.5 Final Pumping*

Fluid was extracted first from one end of the well system then from the other end, using the four channel manifold (see Figure 22, below):

- Shallow transect:
  - The western well segments yielded approximately 330 gallons in 2 hours of pumping.
  - The eastern well segments yielded approximately 330 gallons in 2 hours of pumping.
- Deep transect:
  - The western well segments yielded approximately 330 gallons in 2.5 hours of pumping. The silver well segment produced less water than the others.
  - The eastern well segments yielded approximately 330 gallons in 2.5 hours of pumping.
- Longsect:
  - The western well segments yielded approximately 330 gallons in 1 hour of pumping.
  - The eastern well segments yielded approximately 330 gallons in 1 hour of pumping.

The process appeared to allow all well segments to be freely pumping groundwater at acceptable rates upon completion. Most of the well segments purged a clear color. Also, the pH was measured and appeared to be returning to normal values. Groundwater flux through time along with purging during groundwater sampling will aid the overall completeness of well development. Lower than expected pumping rates and low pH values will indicate the need for possible additional purging to ensure the samples collected are representative. It is our experience that each site is different with respect to the amount of time and the amount of development necessary for truly representative groundwater sample results. One would expect that more permeable soil would allow quick development, but the well development effort is also a function of how much penetration into the formation was made by the drilling fluid. Therefore, data collected during hydraulic testing and sampling were evaluated to confirm development objectives had been achieved.

### 5.4.6 Grouting Operations

After development, the grout lines were attached to a GP350 Geoprobe® grout pump (Figure 22, below). The bentonite and Portland-based expanding grout was added to the pump hopper to facilitate injection into the grout tremie lines. The volumes are added to provide an approximate seal size determined appropriate for the site. For this project, given the spacing between segments, 5-foot seals were installed. Approximately 1.8 gallons per foot were used for seal volume, or 9 gallons total per seal.

**Figure 22. Photographs of Well Development and Grouting**

*Pumping at north end of longsect VWS using manifold (left). Grout injection using tremie lines at east end of shallow transect VWS (right).*

### 5.4.7 Wellhead Completions

Additional finishing tasks include labelling the well systems and installing protective vaults. The systems were labelled with heat-shrink printed labels that provide clear legible notation resistant to fading and extreme conditions. Typical nomenclature indicating the system number, the channel number and color (e.g., A-5S, system A, channel 5 silver) was used. Ten colors were used, which allow easy identification and alpha numeric numbering that is unique.

A total of six 2- x 2- x 2-foot flush-mount vaults were installed (Figure 23, below). Gravel base was placed below the well vault skirts for support. The vaults were finished with a concrete apron measuring approximately 1 foot wide and 4 inches thick. The tubing was coiled inside the vault for future use.

**Figure 23. Well Completion and Waste Storage**

*Well completion with flush-mount vault set in concrete (left). Storage containers for HDD waste (right).*

### 5.4.8 Solid and Liquid Waste Management

Waste from HDD operations and well development (Figure 23, above) were managed as two separate waste streams: solid waste and liquid waste. Cuttings and drilling fluid returns from the directional borings accumulated in the entry and exit pits throughout the drilling process. The drilling slurry waste was removed as necessary and transferred to lined 20-cubic yard roll-off containers for off-site landfill disposal, because the large volume generated was not suitable for surface spreading on site. Due to the high liquid content, the drilling slurry was solidified by mixing with a drying agent. Waste characterization samples were then collected from each roll-off container and submitted for laboratory analysis. The laboratory results were submitted to the landfill as part of the waste profile application. A total of 38 tons of solidified drilling slurry were transported to the landfill for disposal.

Approximately 2,125 gallons of liquid waste were pumped from the VWSs during well development and transferred to a vacuum box for storage. This volume was mostly groundwater, with a smaller portion that included the chemical solutions used during development, which would have been diluted when mixing with groundwater in the well segments. The liquid waste was treated for PFAS removal on site using granular activated carbon (GAC). The on-site treatment system consisted of the following components:

- Transfer pump (5 gallons per minute)
- Sediment filter housing with a 5-micron filter cartridge
- Calgon Flowsorb drum with 180 pounds F400 GAC media.

Composite samples were collected before, during, and after treatment and submitted to a laboratory for PFAS analysis. A second treatment pass was required to achieve discharge limits, prior to discharging the treated groundwater to the ground surface and allowing to infiltrate. No PFAS compounds were detected in the effluent after the second treatment pass.

## 5.5 FIELD TESTING

VWS field testing occurred approximately quarterly for 1 year following installation (fourth quarter 2021 through third quarter 2022). Then an additional four events were completed from fourth quarter 2023 through third quarter 2024. Field testing included:

- Collecting groundwater samples from the VWSs, conventional vertical monitoring wells, and the MLS for PFAS laboratory analysis
- Hydraulic testing of the VWSs
- SWTT in the VWSs
- A-DTS testing of the horizontal and vertical fiber optic cables
- Manual water level measurements from the conventional vertical monitoring wells
- High-resolution water level data from pressure transducer dataloggers deployed in the conventional vertical monitoring wells.

The completed project schedule for the VWS installations and field testing is presented in Table 8, below.

**Table 11. Completed Project Schedule**

| | 20Q3 | 20Q4 | 21Q1 | 21Q2 | 21Q3 | 21Q4 | 22Q1 | 22Q2 | 22Q3 | 22Q4 | 23Q1 | 23Q2 | 23Q3 | 23Q4 | 24Q1 | 24Q2 | 24Q3 | 24Q4 |

| Task 6: Reporting, Deliverables, and Technology Transfer | | SSM | G/NG | DP | | | | TT | TT | TT | | | | | | | | FR |
| 1 Year of Additional Performance Monitoring | | | | | | | | | | | | | | | | | | |

**Notes:**
DP = Demonstration Plan (Divine et al. 2021)
FR = Final Report
G/NG = Go/No Go Recommendation Memo (Divine et al. 2021b)
SSM = Site Selection Memo (Divine et al. 2021a)
TT = technology transfer

After all field activities for this project have concluded, the Michigan Army National Guard (MIARNG) has agreed that the VWSs will remain at the GAAF for potential use in evaluating performance of future technology demonstrations designed to treat the soils and groundwater in the Building 1160 source area.

## 5.6 MONITORING METHODS AND RESULTS

Pre-design characterization activities were conducted using vertical drilling methods, prior to installing the VWSs. The results were used to finalize the design of the VWSs (Section 5.2). After the VWSs were installed, monitoring events were conducted approximately quarterly. Select vertical monitoring wells and the MLS CMT well were also included in the monitoring events, for comparison to results from the VWSs.

These data were sufficient to validate the technology performance under real-world conditions and present relevant and significant spatial and temporal variations to complete a thorough evaluation. Table 9, below, describes the number and type of samples that were collected during each phase of this project, along with the analytical methods. Existing site-wide sampling and laboratory procedures were followed to meet the quality assurance requirements. Field duplicates and equipment blanks were included quarterly. All samples were uniquely labelled and documented on chain-of-custody forms. All field activity was recorded in field logs and with photographs.

**Table 12. Total Number and Types of Samples Collected**

| Work Phase | Matrix | Number of Samples | Analysis | Method |
|---|---|---|---|---|
| Vertical characterization | Soil | 31 | PFAS – DoD QSM | LC/MS/MS: USEPA 537 Modified DoD QSM 5.1 |
| | | 8 | PFAS – TOP Assay | TOP assay |
| | | 15 | PFAS – LC-QTOF | LC-QTOF mass spectroscopy |
| | | 50 (U. Guelph, from golden spike boring) 15 (contract lab, splits from golden spike boring, other borings) | Grain Size | ASTM International (ASTM) Method D6913/D6913M-17 Standard Test Methods for Particle-Size Distribution (Gradation) of Soils Using Sieve Analysis (or equivalent method) |
| | GW | 41 | PFAS - DoD QSM | LC/MS/MS:[a] USEPA 537 Modified DoD QSM 5.1 |
| Performance monitoring – First four events | GW | 208 | PFAS – DoD QSM | LC/MS/MS:[a] USEPA 537 Modified DoD QSM 5.1 |
| Performance monitoring – Four additional events | GW | 123 | PFAS – DOD QSM | LC/MS/MS:[a] USEPA Method 1633 |

**Notes:**
[a] LC/MS/MS = liquid chromatography with tandem mass spectroscopy
1. Performance monitoring count includes eight quarterly events for VWS, CMT well system, and monitoring wells.
2. Grain-size analysis counts include samples collected at two additional continuous core locations in addition to splits from the golden spike boring submitted to the contract lab.
3. Sample counts above include QA/QC samples.
GW = groundwater
QSM = quality systems manual

Monitoring methods and results from various field activities conducted after the VWSs were installed are presented in Sections 5.6.1 through 5.6.8.

### 5.6.1 VWS Sampling

VWSs are sampled using typical monitoring well sampling techniques. For shallow water table elevations, a peristaltic pump can be used and can be attached directly to the well riser for smaller diameter risers or a separate sampling line can be inserted for larger diameter risers. For deeper systems, a Waterra inertial pumping system or a gas drive pumping system such as a double-valve pump or small-diameter bladder pump can be used for sampling.[4,5,6]

Other suitable pump options are also available, depending on the specific VWS design parameters. Well volumes can be calculated to determine required purge volumes and monitoring of field parameters (e.g., dissolved oxygen, pH, redox potential, electrical conductivity) can be used to confirm the water quality is stable prior to sample collection. Usually, a nearby monitoring well is sufficient to estimate water table elevation for well volume calculations. This method of gauging a nearby monitoring well was utilized to determine well volumes for this project. Depth to water cannot be measured precisely using depth-to-water tapes in the horizontal VWS ports; however, static vacuum can be an indicator of approximate water table elevation. Static vacuum can be measured by drawing water to the surface using a peristaltic pump (or others) and closing the line or stopping the pump and allowing the system to equalize. The static vacuum in the line, measured with a vacuum gauge or manometer, is equivalent to the water table depth. The term static vacuum is used to emphasize vacuum in the tubing must be allowed to equalize, because the vacuum in the line when the pump is engaged and water is flowing can be significantly different. The measurement is relative to the gauge location and height. Multiple wells can be measured from the same location and gradient across a wells system can be determined. The accuracy of the static vacuum method for measuring groundwater elevation is slightly less than that of current vertical instruments. Sampling activities were completed by local field technicians that are familiar with the MDEQ and sampling protocol. MDEQ has online documents indicating suitable techniques for PFAS sampling.[7]

Groundwater samples were collected from the VWSs quarterly using a peristaltic pump and were analyzed for PFAS. Low-flow sampling methodology consistent with Arcadis' TGI was used to sample the VWSs for PFAS compounds. Geochemical water quality parameters were monitored and recorded during groundwater sampling. Groundwater sampling logs are provided in Appendix I. PFAS groundwater analytical results from the VWSs are presented in Tables 13 and 14 and the laboratory analytical reports are provided in Appendix C.

**Notes:**
1. Bold indicates that sample results were reported above the laboratory reporting detection limit of detection.

**Abbreviations:**
FD = Field Duplicate Sample
ft bgs - feet below ground surface
ID - Identification
N = Normal Field Sample
ng/L - nanograms per liter
PFAS - per- and polyfluoroalkyl substances
SU - standard unit
-- Not analyzed

**Qualifiers:**
B - Detected in the method blank
H - Out of holding time
J - estimated value between the limit of quantitation and the method detection limit.
L - LCS/LCSD failure
M - Manual integration occurred due to incorrect auto integration
Q - Indicates a non-compliant QC Result (see Q flag application report: surrogate failure)
S - Indicates a non-compliant QC Result (see Q flag application report: MS/MSD failure)
U - Not detected at or above the limit of quantitation

**Notes:**
1. Bold indicates that sample results were reported above the laboratory reporting detection limit of detection.

**Abbreviations:**
FD = Field Duplicate Sample
ft bgs - feet below ground surface
ID - Identification
N = Normal Field Sample
ng/L - nanograms per liter
PFAS - per- and polyfluoroalkyl substances
SU - standard unit
-- Not analyzed

**Qualifiers:**
B - Detected in the method blank
H - Out of holding time
J - estimated value between the limit of quantitation and the method detection limit.
L - LCS/LCSD failure
M - Manual integration occurred due to incorrect auto integration
Q - Indicates a non-compliant QC Result (see Q flag application report: surrogate failure)
S - Indicates a non-compliant QC Result (see Q flag application report: MS/MSD failure)
U - Not detected at or above the limit of quantitation

**Notes:**
1. Bold indicates that sample results were reported above the laboratory reporting detection limit of detection.

**Abbreviations:**
FD = Field Duplicate Sample
ft bgs - feet below ground surface
ID - Identification
N = Normal Field Sample
ng/L - nanograms per liter
PFAS - per- and polyfluoroalkyl substances
SU - standard unit
-- Not analyzed

**Qualifiers:**
B - Detected in the method blank
H - Out of holding time
J - estimated value between the limit of quantitation and the method detection limit.
L - LCS/LCSD failure
M - Manual integration occurred due to incorrect auto integration
Q - Indicates a non-compliant QC Result (see Q flag application report: surrogate failure)
S - Indicates a non-compliant QC Result (see Q flag application report: MS/MSD failure)
U - Not detected at or above the limit of quantitation

**Notes:**
1. Bold indicates that sample results were reported above the laboratory reporting detection limit of detection.

**Abbreviations:**
FD = Field Duplicate Sample
ft bgs - feet below ground surface
ID - Identification
N = Normal Field Sample
ng/L - nanograms per liter
PFAS - per- and polyfluoroalkyl substances
SU - standard unit
-- Not analyzed

**Qualifiers:**
B - Detected in the method blank
H - Out of holding time
J - estimated value between the limit of quantitation and the method detection limit.
L - LCS/LCSD failure
M - Manual integration occurred due to incorrect auto integration
Q - Indicates a non-compliant QC Result (see Q flag application report: surrogate failure)
S - Indicates a non-compliant QC Result (see Q flag application report: MS/MSD failure)
U - Not detected at or above the limit of quantitation

**Notes:**
1. Bold indicates that sample results were reported above the laboratory reporting detection limit of detection.

**Abbreviations:**
FD = Field Duplicate Sample
ft bgs - feet below ground surface
ID - Identification
N = Normal Field Sample
ng/L - nanograms per liter
PFAS - per- and polyfluoroalkyl substances
SU - standard unit
-- Not analyzed

**Qualifiers:**
B - Detected in the method blank
H - Out of holding time
J - estimated value between the limit of quantitation and the method detection limit.
L - LCS/LCSD failure
M - Manual integration occurred due to incorrect auto integration
Q - Indicates a non-compliant QC Result (see Q flag application report: surrogate failure)
S - Indicates a non-compliant QC Result (see Q flag application report: MS/MSD failure)
U - Not detected at or above the limit of quantitation

**Notes:**
1. Bold indicates that sample results were reported above the laboratory reporting detection limit of detection.

**Abbreviations:**
FD = Field Duplicate Sample
ft bgs - feet below ground surface
ID - Identification
N = Normal Field Sample
ng/L - nanograms per liter
PFAS - per- and polyfluoroalkyl substances
SU - standard unit
-- Not analyzed

**Qualifiers:**
B - Detected in the method blank
H - Out of holding time
J - estimated value between the limit of quantitation and the method detection limit.
L - LCS/LCSD failure
M - Manual integration occurred due to incorrect auto integration
Q - Indicates a non-compliant QC Result (see Q flag application report: surrogate failure)
S - Indicates a non-compliant QC Result (see Q flag application report: MS/MSD failure)
U - Not detected at or above the limit of quantitation

**Notes:**
1. Bold indicates that sample results were reported above the laboratory reporting detection limit of detection.

**Abbreviations:**
FD = Field Duplicate Sample
ft bgs - feet below ground surface
ID - Identification
N = Normal Field Sample
ng/L - nanograms per liter
PFAS - per- and polyfluoroalkyl substances
SU - standard unit
-- Not analyzed

**Qualifiers:**
B - Detected in the method blank
H - Out of holding time
J - estimated value between the limit of quantitation and the method detection limit.
L - LCS/LCSD failure
M - Manual integration occurred due to incorrect auto integration
Q - Indicates a non-compliant QC Result (see Q flag application report: surrogate failure)
S - Indicates a non-compliant QC Result (see Q flag application report: MS/MSD failure)
U - Not detected at or above the limit of quantitation

**Notes:**
1. Bold indicates that sample results were reported above the laboratory reporting detection limit of detection.

**Abbreviations:**
FD = Field Duplicate Sample
ft bgs - feet below ground surface
ID - Identification
N = Normal Field Sample
ng/L - nanograms per liter
PFAS - per- and polyfluoroalkyl substances
SU - standard unit
-- Not analyzed

**Qualifiers:**
B - Detected in the method blank
H - Out of holding time
J - estimated value between the limit of quantitation and the method detection limit.
L - LCS/LCSD failure
M - Manual integration occurred due to incorrect auto integration
Q - Indicates a non-compliant QC Result (see Q flag application report: surrogate failure)
S - Indicates a non-compliant QC Result (see Q flag application report: MS/MSD failure)
U - Not detected at or above the limit of quantitation

**Notes:**
1. Bold indicates that sample results were reported above the laboratory reporting detection limit of detection.

**Abbreviations:**
FD = Field Duplicate Sample
ft bgs - feet below ground surface
ID - Identification
N = Normal Field Sample
ng/L - nanograms per liter
PFAS - per- and polyfluoroalkyl substances
SU - standard unit
-- Not analyzed

**Qualifiers:**
B - Detected in the method blank
H - Out of holding time
J - estimated value between the limit of quantitation and the method detection limit.
L - LCS/LCSD failure
M - Manual integration occurred due to incorrect auto integration
Q - Indicates a non-compliant QC Result (see Q flag application report: surrogate failure)
S - Indicates a non-compliant QC Result (see Q flag application report: MS/MSD failure)
U - Not detected at or above the limit of quantitation

**Notes:**

1. Bold indicates that sample results were reported above the laboratory reporting detection limit of detection.

2. Samples from performance monitoring event #2 were oxidized twice as a QC check by the lab, resulting in two Post analysis results (Post and Post-2)

**Abbreviations:**

ft bgs - feet below ground surface
ID - Identification
ng/L - nanograms per liter
PFAS - per- and polyfluoroalkyl substances

**Qualifiers:**
J - estimated value between the limit of quantitation and the method detection limit.
U - Not detected at or above the limit of quantitation.

**Notes:**

1. Bold indicates that sample results were reported above the laboratory reporting detection limit of detection.

2. Samples from performance monitoring event #2 were oxidized twice as a QC check by the lab, resulting in two Post analysis results (Post and Post-2)

**Abbreviations:**

ft bgs - feet below ground surface
ID - Identification
ng/L - nanograms per liter
PFAS - per- and polyfluoroalkyl substances

**Qualifiers:**
J - estimated value between the limit of quantitation and the method detection limit.
U - Not detected at or above the limit of quantitation.

### 5.6.2 VWS Hydraulic and Tracer Testing

Hydraulic testing was completed for VWS well screens to estimate groundwater flux and local K values. Individual isolated horizontal well screens within the shallow (B1, S2, Y3, G4, M5, O6, R7, and P8) and deep (B1, S2, Y3, G4, M5, O6, R7, and P8) VWS transects were tested using the inflow (falling head) method. Select deep VWS transect intervals (M5, O6, R7, and P8) were also tested using the pneumatic slug testing method. The VWS hydraulic testing results are provided in Appendix D. As discussed further in Section 7.2, it was concluded that skin effects were likely present, with slug testing results biased low and unreliable due to friction losses associated with the geotextile membrane used in the VWS construction. Therefore, estimating local K using VWS screens for slug testing is not recommended.

Point-dilution tracer tests were also completed at each VWS screen to provide local measures of the darcy flux. A TGI was previously developed and presented with the Go/No-Go Decision Recommendation (Divine et al. 2021b). The TGI provides detailed field procedures for performing single-well point dilution tracer tests specifically within a VWS. An Excel-based tracer test interpretation tool is also included as part of the TGI.

### 5.6.3 Active Fiber Optic Distributed Temperature Sensing Testing

Temperature data were collected using a four-channel Silixa ULTIMA-S™ DTS configured for a maximum fiber length of 1.8 kilometers. The A-DTS has sampling, spatial, and temporal resolutions of 0.125 meter, 0.29 meter, and +/- 0.01 °C, respectively. Data were collected using the internal double-ended calibration routine for slope correction, and a calibration bath with 45 feet of unheated cable and two PT100 temperature sensors for the offset calibration. Distributed temperature measurements along the full cable length were collected continuously throughout the A-DTS tests. This typically involved 30 minutes before heating to capture the background temperature profile, and an active heating phase at 10 watts per meter (W/m) for 24 hours.

An offset calibration is conducted after data collection and the data are averaged through time to reach a temperature resolution of approximately +/- 0.03 °C. The in-situ thermal conductivity is calculated from each depth using the rate of temperature increase (during the heating period) and the infinite line source analytical theory presented by Carslaw and Jaeger (1959). If the thermal conductivity of the surrounding aquifer material is known, the flux can be estimated from the A-DTS apparent thermal conductivity using the approach presented by Maldaner et al. (2019). This approach uses numerical modelling to develop an empirical relationship for a particular test geometry and parameters to quantify groundwater flow rates with modelling details provided below.

The A-DTS testing proposed in this project deviates from the fractured rock application presented in Maldaner et al. (2019); therefore, preliminary numerical modelling was conducted to assess the feasibility of measuring flux in the unconsolidated aquifer with A-DTS. The model scenario was developed using representative site parameters and filters to represent the spatial and temperature resolution of the A-DTS unit, and the results are presented in Divine et al. (2021b). In summary, three scenarios were simulated to assess the effect of groundwater flow on the apparent thermal conductivity that can be estimated from an A-DTS test. These scenarios include a saturated homogeneous porous medium with no groundwater flow, the same saturated homogeneous porous medium with groundwater flow, and a scenario with groundwater flow and a horizontal layer with a K of half an order of magnitude higher than the surrounding sediment.

The modelling results demonstrate that the changes in flow through layers with contrasting K expected at the GAAF are measurable with the A-DTS technique, suggesting a good possibility of being able to apply A-DTS at the GAAF to estimate groundwater flux.

#### *5.6.3.1 Numerical Modelling for Groundwater Flux Estimation*

As the approach presented by Maldaner et al. (2019) requires an empirical relationship using the site-specific and test parameters, additional modelling was needed to develop this relationship to estimate groundwater flux. This involved numerous A-DTS simulations under a wide range of groundwater flow rates using representative test geometry and physical parameters.

The numerical modelling is based on the finite element numerical model Heatflow-Smoker that represents 3-D groundwater flow and heat transport in a homogeneous and isotropic porous medium (Molson et al. 1992). For this project, the full 3D domain has dimensions of 4 x 4 x 4 meters, with a fiber optic cable discretized vertically in the center of the domain.

The physical and thermal parameters used in the numerical model are presented in Tables 15 and 16, below. The thermal conductivity values for the sediment were informed from the lab thermal conductivity measurements using a TEMPOS Thermal Properties Analyzer and SH-3 dual-needle probe. The sediment samples were taken from three vertical boreholes (SB02, SB03, and SB-04) and the samples were fully saturated before testing (Tables 17, 18, and 19, below). The remainder of the values were based on pre-existing field or lab measurements or reasonable literature values. The model parameters presented in Table 16, below, represent reasonable site parameters. The hydraulic gradient is fixed at 0.0023 and the flow rate is changed by varying the K from $1x10^{-5}$ to $1x10^{-3}$ meter per second (m/s). The initial and boundary temperatures are set to 10 °C, which represents the average ambient groundwater temperature measured at the GAAF.

**Table 15. Physical and Thermal Parameters Used in the Numerical Model**

| Model Component | K | Thermal Conductivity | Specific Heat Capacity | Density | Porosity |
|---|---|---|---|---|---|
| | [m/s] | [W/mK] | [J/kgK] | [kg/m$^3$] | [-] |
| Solids | $1x10^{-3}$ - $1x10^{-5}$ | 3.97 | 1,041 | 2,156 | 0.48 |
| Water | NA | 0.57 | 4,187 | 1,000 | NA |

**Notes:**
- = unitless
J/kgK = joule per kilogram kelvin
kg/m$^3$ = kilogram per cubic meter
NA = not applicable
W/mK = watt per meter kelvin

**Table 16. Model Parameters**

| Model Parameters | |
|---|---|
| Hydraulic gradient [meter per meter] | 0.0023 |
| Initial temperature [°C] | 10 |
| Temperature at boundary [°C] | 10 |
| Power input [W/m] | 10 |
| Heating duration [hours] | 24 |

The laboratory measurements indicated an average effective thermal conductivity of the sediment of 2.5 W/mK. This value typically represents the no-flow apparent thermal conductivity of the aquifer system under zero-gradient (no flow) conditions. However, many of the baseline results in the observed A-DTS data (presented below) showed a consistently lower apparent thermal conductivity, around 1.9 W/mK. This discrepancy suggests a potential bias toward higher values in the lab measurements. This bias could be attributed to differences in compaction/porosity or saturation between the lab samples and the in-situ sediment. Consequently, porosity within the numerical model was adjusted during calibration to bring the effective thermal conductivity of the sediment in the model down to match the lower value observed in the A-DTS field data (1.9 W/mK).

The model outputs allow the empirical relationship between the in-situ apparent thermal conductivity and the groundwater flux (specific discharge) at each of the A-DTS measurement intervals along the fiber optic cable. A square root function was fit to the data to establish the empirical relationship:

$$q = \beta\sqrt{(\lambda_a - \lambda_0)}$$

Where:

q = groundwater flux

β = fitting parameter determined using least squares

$\lambda_a$ = A-DTS derived apparent thermal conductivity

$\lambda_0$ = apparent thermal conductivity where q=0 (1.9 W/mK, in this case).

Based on the numerical modelling and least squares fit, β was determined to be $2.93 \times 10^{-6}$ for this A-DTS test geometry and parameters (Figure 24, below).

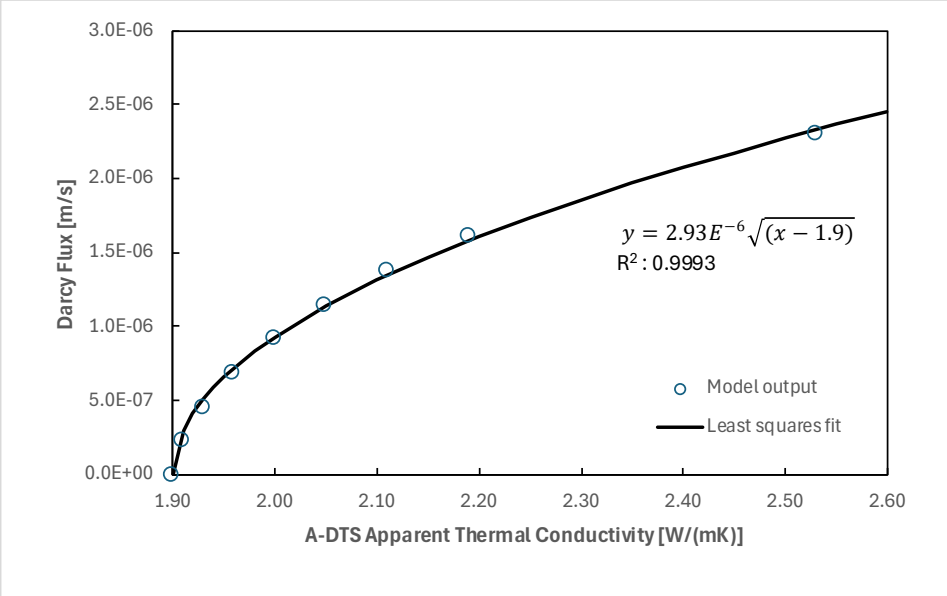

**Figure 24. Model Output and Least Squares Fit to Estimate Groundwater Flux from the A-DTS Apparent Thermal Conductivity Data**

Using the site-specific empirical relationship, the specific discharge, q, for each monitoring interval along the fiber optic cable can be estimated from the apparent thermal conductivity value for each snapshot. As this provides hundreds of measurements along the cable, the discrete values were averaged along the 10-foot screened intervals to provide a more direct comparison to the other flux measurement methods applied in this study.

#### *5.6.3.2 A-DTS Groundwater Flux from Horizontal Deployments*

As described in Section 5.4, two horizontal composite fiber optic cables were deployed: one integrated into the shallow transect VWS and the other a stand-alone cable running parallel to the VWS with a horizontal offset of approximately 12 feet. The two cables were spliced together to form a continuous network, allowing simultaneous A-DTS testing of both cables. Nine A-DTS sampling events were conducted: October and December 2021; April, June, and August 2022; October 2023; and January, April, and July 2024. For each event, 30 minutes of background temperature data were recorded, followed by 24 hours of active heating at an output of 10 W/m. Figures 25 and 26, below, present data montages from the horizontal fiber optic A-DTS installs in the stand-alone and shallow transect VWSs, respectively. These include continuous profiles of apparent thermal conductivity from the A-DTS heating data, the resultant groundwater flux for every DTS sampling interval using the empirical relationship shown on Figure 24 (above), and flux averaged over the 10-foot well screen intervals for the shallow transect. The mean flux value across the screen intervals for both the stand-alone and VWS fiber optic installations are presented in Tables 20 and 21 (below), respectively, with the percent difference between the two installations presented in Table 22, below.

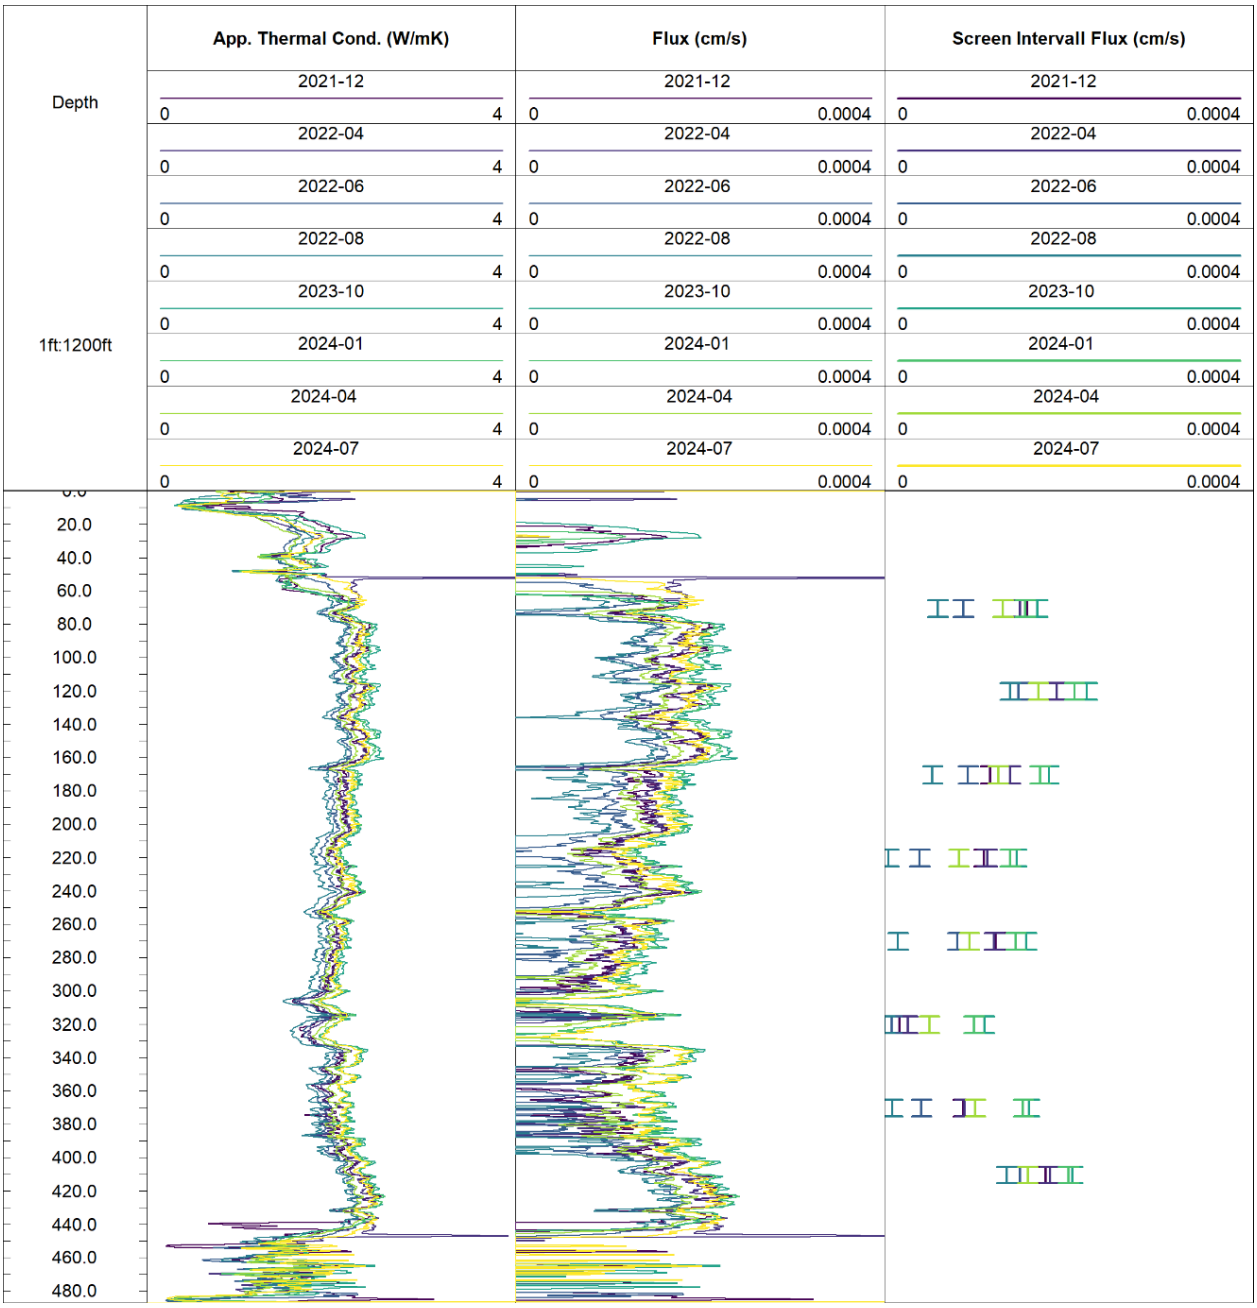

**Figure 25. A-DTS Result Montage for the Stand-Alone Horizontal Fiber Optic Cable**

*Montage includes (from left to right) distance (from eastern wellhead), apparent thermal conductivity, groundwater flux for each sampling interval on the DTS (12.5 cm along cable), and groundwater flux averaged across each 10-foot well screen interval.*

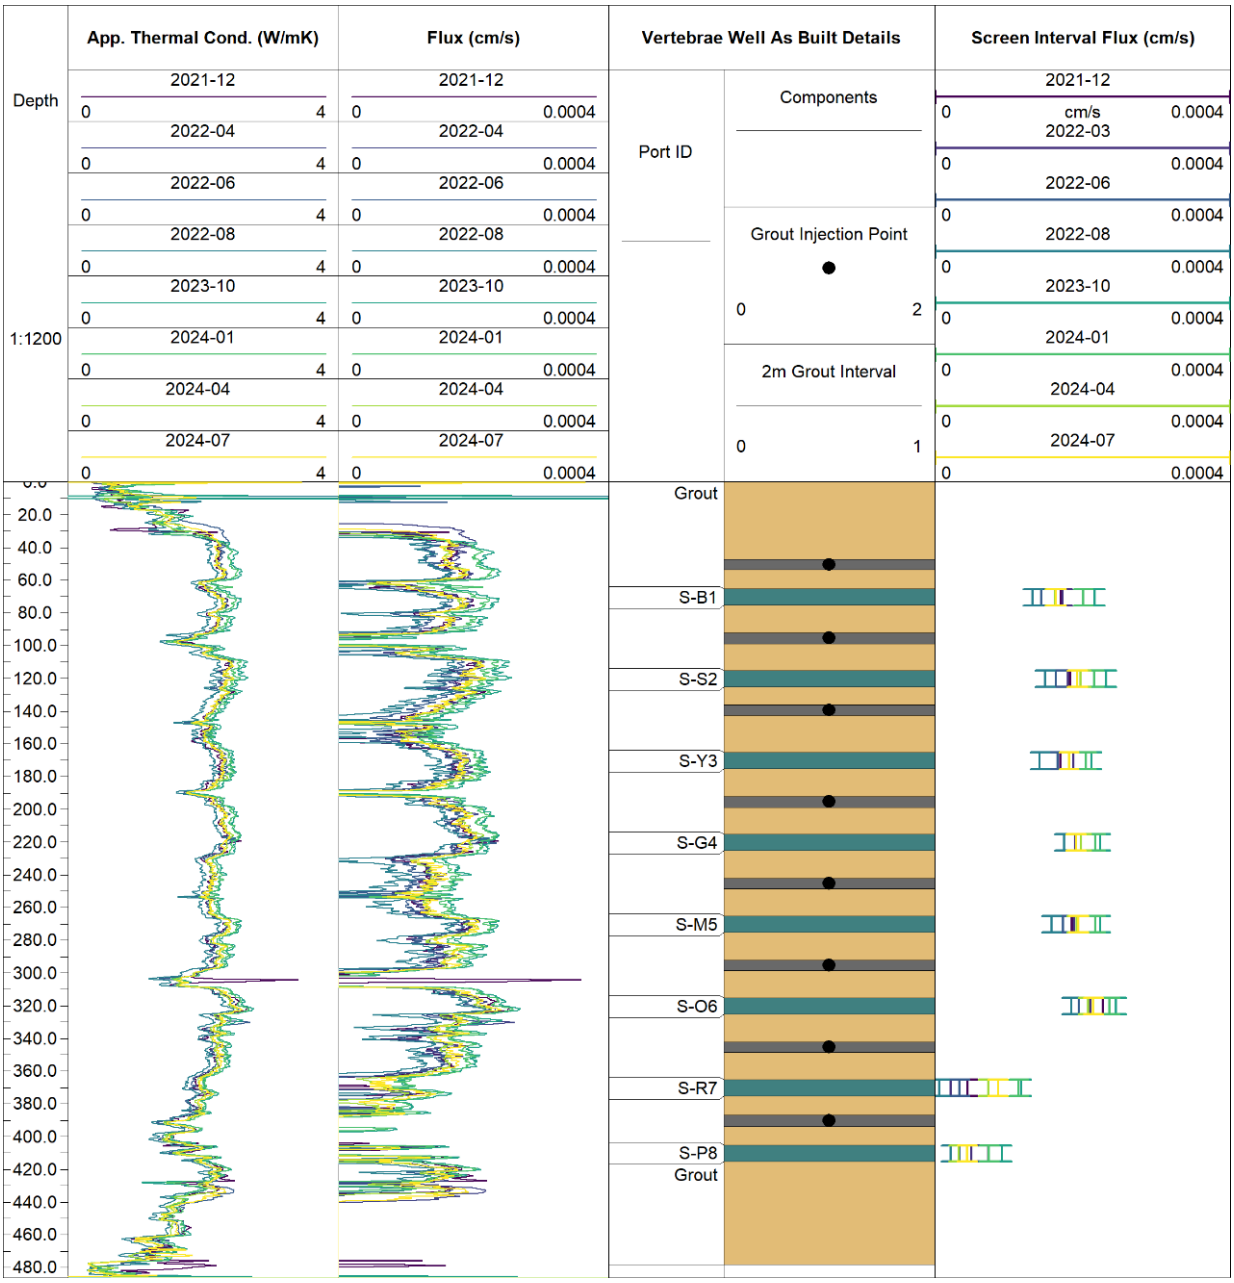

**Figure 26. A-DTS Result Montage for the Horizontal Fiber Optic Cable Integrated into the Shallow VWS**

*Montage includes (from left to right) distance (from eastern wellhead), apparent thermal conductivity, groundwater flux for each sampling interval on the DTS (12.5 cm along cable), VWS completion details, and groundwater flux averaged across each 10-foot well screen interval.*

**Note:**

1. The colors represent a gradient showing flow magnitude difference comparing the VWS A-DTS test relative to the standalone A-DTS test. The red indicates a decreased measured flow in the VWS test relative to the standalone test, the blue represents an increase, and the white represents no change.

The flux results averaged across the well screen intervals from the A-DTS tests show a reasonable match to other flux estimate methods, and also between the stand-alone installation and installation that is co-deployed with the VWS. In nearly all ports, there was an elevated flux measured from the cable co-deployed with the VWS screen, with most ports experiencing an approximately 30 to 70% enhancement relative to the stand-alone cable (Table 22, above). The exception is the two ports on the westernmost end of the shallow transect VWS, S-R7 and S-P8, which both show a measurable decrease in flux. The increase in flux observed in most of the ports is likely attributable to flow convergence from the open tubing intervals in the VWS screen, creating a high K interval within the aquifer. This convergence is accounted for in other flux methods using an enhancement factor, and these A-DTS results could provide a means to quantify the enhancement factor for similar deployments. The two ports that measure a consistent decrease in flux (S-R7 and S-P8) appear to have been impacted by grout placement over the screened intervals. This is demonstrated in the following section where the DTS data were used to identify the position and length of grout seals. This grout interference would decrease the A-DTS flux estimates in these intervals in two ways:

- The permeability of the grout materials is significantly lower and one would expect the flux within grouted intervals to be lower than in the non-grouted intervals.
- The grout likely has a lower effective thermal conductivity, which would bias the flux estimates low using the modelled empirical relationship to estimate flux shown on Figure 24, above. This effect can be observed by the regular decreases in apparent thermal conductivity and flux near grouted intervals shown on Figure 26, above.

#### *5.6.3.3 A-DTS Groundwater Flux from Vertical Deployments*

At the vertical fiber optic borehole locations (DTS-1, DTS-2, DTS-3, DTS-4; Figure 27), A-DTS data were collected at each sampling event described above. For the first five field events, data were collected by connecting the four individual locations using surface composite fiber optic cable to form a continuous network. This allowed simultaneous testing of all four locations but had an unanticipated data quality issue resulting from the significant temperature changes of the surface heating wires during the 24-hour heating test, leading to a thermal imprint in all of the temperature data collected. These fluctuations were attributed to daily temperature shifts and varying degrees of direct sunlight exposure, which in turn altered the electrical resistance of the copper heating wires. The resulting resistance changes impacted the power output throughout the network, affecting the downhole data as well. Initially, it was unclear what was causing this thermal imprint on the data. Once discovered, several attempts to mitigate the effect were implemented, including using separate white heating wires and heavier gauge heating wire (12 vs. 18 American Wire Gauge), but this was not sufficient to eliminate the thermal imprint. Given that burying the surface cable was not feasible at the GAAF due to the cost and presence of underground utilities, a decision was made to run individual A-DTS tests at the four locations. This reduced the data collection efficiency but resulted in significantly higher data quality. In October 2021, a full 24-hour individual test was run at the DTS-2 location with excellent results. Subsequently, in January 2024, there was an attempt to perform individual A-DTS tests at all four locations. However, due to a winter storm and substantial snow accumulation from drifts and snow removal operations, only two locations (DTS-2 and DTS-4) were accessible and tests were conducted. In April 2024, A-DTS tests were successfully carried out at all 4 locations, and in July 2024, successful tests were collected at DTS-1, DTS-2 and DTS-3 locations. The results from all successful tests, presented as apparent thermal conductivity and groundwater flux measurements, are shown in Figure 28, below.

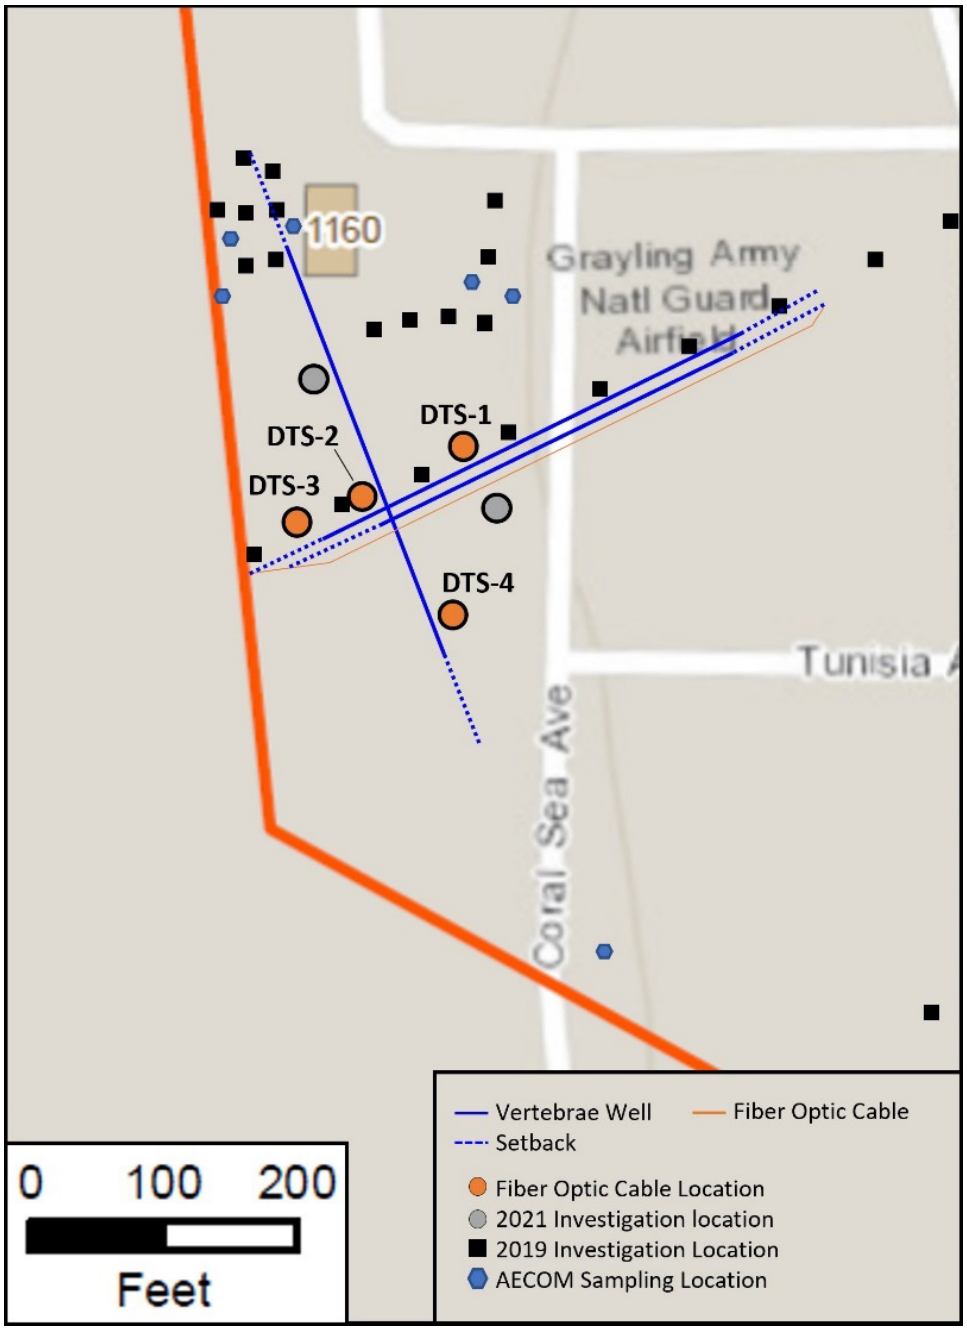

**Figure 27. GAFF Site Map Showing the Location of the Four Vertical A-DTS Locations (DTS-1, DTS-2, DTS-3, and DTS-4)**

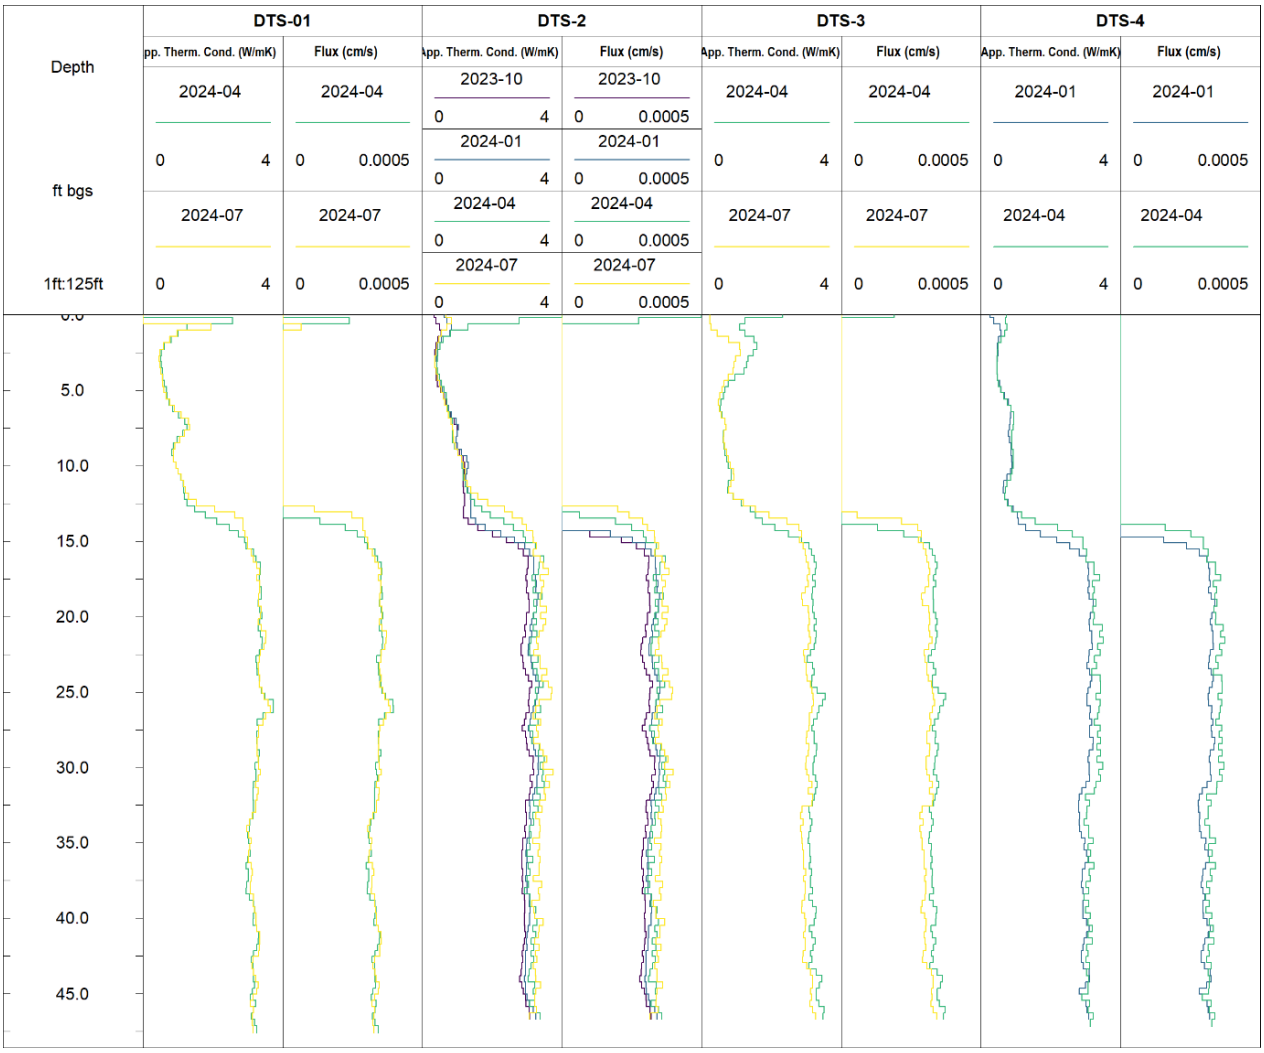

**Figure 28. A-DTS Result Montage for the Vertical Fiber Optic Cable Installations**

*Montage includes (from left to right) depth (feet bgs), and apparent thermal conductivity and groundwater flux data for the DTS-1, DTS-2, DTS-3 and DTS-4 locations.*

The vertical A-DTS tests successfully generated detailed vertical profiles of groundwater flux at 4 locations across the site. Subtle changes in the apparent thermal conductivity above the water table (generally around 12-13 ft below ground surface based on Figure 28) likely correspond to variations in moisture content in the vadose zone, potentially indicating an effective means for measuring vadose zone saturation or recharge rates. The apparent thermal conductivity and flux results below the water table are quite repeatable from snapshot to snapshot, though minor variation from snapshot to snapshot is recorded, likely due to changes in the hydraulic gradient magnitude. While fairly uniform flux with depth is measured, there is indication of several minor preferential flow layers, such as the small peak in apparent thermal conductivity around 26 ft below ground surface, in DTS-1, DTS-2 and DTS-3.

#### *5.6.3.4 Assessing Grout Seal Location and Extent using A-DTS Data*

Temperature data were used to assess the final position and extent of the cement grout that was injected between ports in the shallow transect VWS. This was done using two approaches. The first approach used the natural thermal signature of the curing Portland cement in the grout mixture, which generates heat, and involved a passive temperature snapshot approximately 20 hours after injecting the grout between the VWS monitoring intervals. The second approach used the contrasting thermal properties of the grout material relative to the sediment to identify grout in the A-DTS test result.

For the passive temperature approach, the natural background temperature trend along the fiber was removed by selecting points along the temperature baseline away from thermal anomalies and fitting a cubic spline through the points. This cubic spline was subtracted from the temperature dataset to highlight temperature deviations away from the background temperature, which we hypothesize are due to curing of the Portland cement in the grout. Figure 29, below, shows the background temperature profile along the fiber with the cubic spline. The interpreted grout seal position and length from this method are presented in Table 23, below. The active heating approach using the thermal responses in the A-DTS apparent thermal conductivity data provided similar results to the passive test and serves as an alternative approach if the initial cement grout curing phase has been missed. The apparent thermal conductivity profiles from the A-DTS test produce a clear decrease in thermal conductivity where the grout seals exist, due to the lower thermal conductivity of the grout materials relative to the aquifer materials (see apparent thermal conductivity dips shown on Figure 26, above). To visualize this, Figure 29, below, provides the apparent thermal conductivity plot with an upper limit of 1.9 W/mK, representing the expected effective thermal conductivity of the sediment. A-DTS apparent thermal conductivity values that fall below this value indicate the likely position of grout seals. Examples of these locations are highlighted using arrows in Figure 29, below. There is good agreement between the passive temperature grout seal placement and the active heating assessment, although the seals create a shorter response in the latter method.

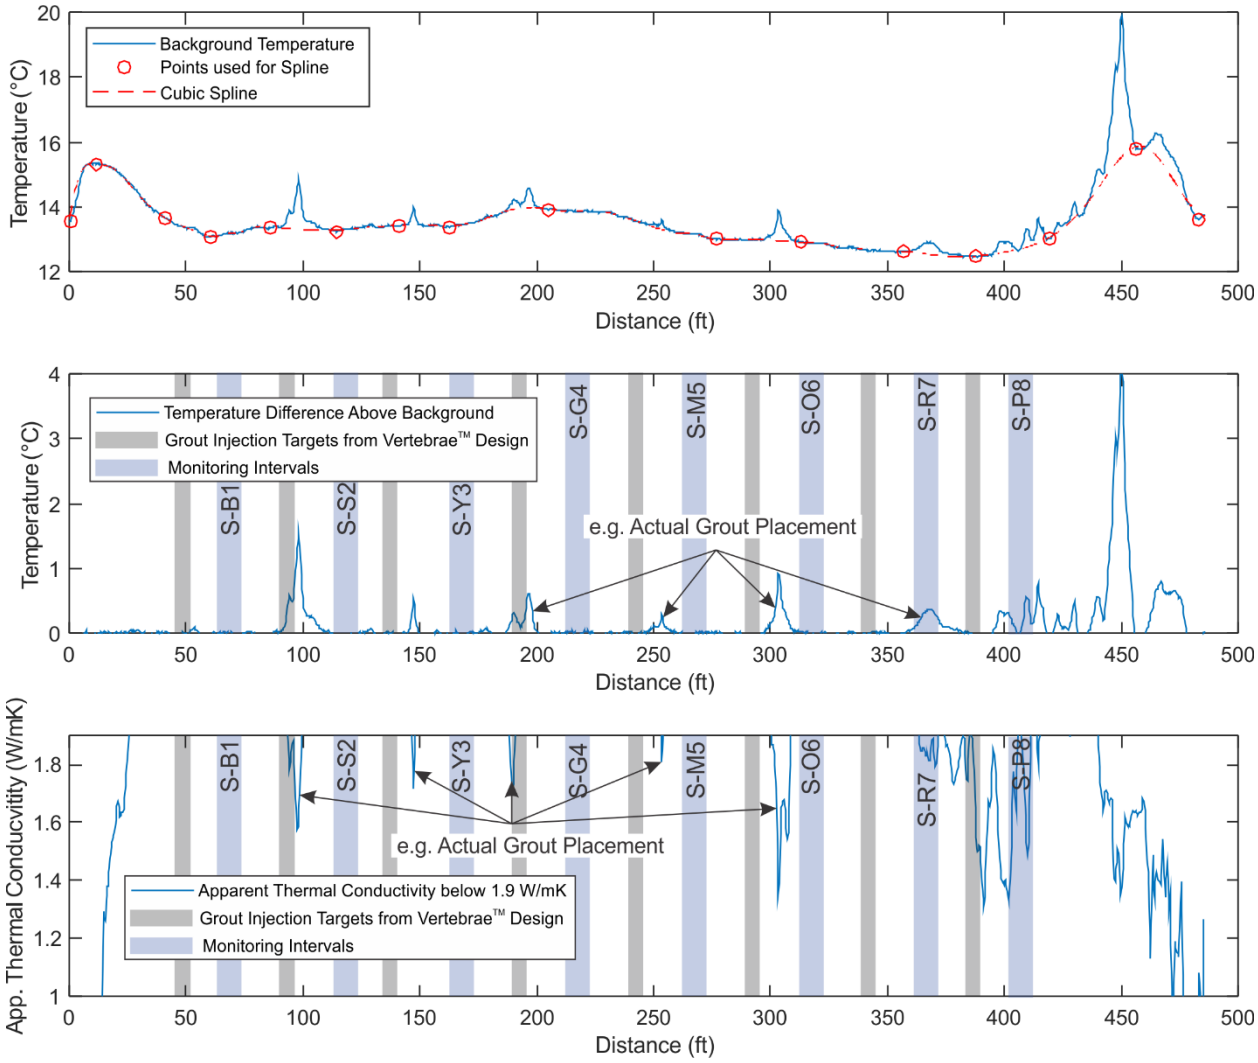

**Figure 29. DTS Temperature Data from the Fiber Optic Cable Installed with the VWS for the Shallow Transect Location**

The temperature data approximately 20 hours after grout injection. Upper: raw temperature data showing cubic spline fit to remove the background trend, Middle: the temperature above background, used to associate the location of injected grout intervals. The targeted VWS grout injection intervals are represented by grey vertical bars and the monitoring intervals are represented by blue vertical bars with the Port ID overlain. Lower: the apparent thermal conductivity A-DTS data from April 2022 showing the anomalously low values that correspond to the grout locations. Note the maximum y-axis value of 1.9 W/mK for the lower plot was used to emphasize the thermal conductivity data below the interpreted sediment value of 1.9 W/mK. There is overall good agreement between the two thermal methods for assessing grout position. Arrows point to example thermal responses corresponding to the actual grout position.

**Table 23. Seal Position and Length Based on Temperature Response Measured with DTS**

| Start Distance | End Distance | Maximum Enhancement Greater Than Background | Inferred Grout Length |
|---|---|---|---|
| feet from wellhead | feet from wellhead | °C | feet |
| 91.3 | 108.3 | 1.51 | 17.0 |
| 144.8 | 149.5 | 0.53 | 4.7 |

| 395.4 | 478.1 | 4.36 | 82.7 |

### 5.6.4 Multilevel System Sampling

Groundwater samples from the installed MLS were collected quarterly and analysed for PFAS, contemporaneous with the VWS groundwater sampling events. Low-flow sampling methodology consistent with Arcadis' TGI was used to sample the monitoring wells for PFAS compounds. Geochemical water quality parameters were monitored and recorded during groundwater sampling. Groundwater sampling logs are provided in Appendix I. PFAS groundwater analytical results from the MLS are presented in Tables 13 and 14, and the laboratory analytical reports are provided in Appendix C.

### 5.6.5 Monitoring Well Sampling

Groundwater samples from installed conventional monitoring wells were collected quarterly and analyzed for PFAS, contemporaneous with the VWS and MLS groundwater sampling events. Low-flow sampling methodology consistent with Arcadis' TGI were used to sample the monitoring wells for PFAS compounds. Geochemical water quality parameters were monitored and recorded during groundwater sampling. Groundwater sampling logs are provided in Appendix I. PFAS groundwater analytical results from the monitoring wells are presented in Tables 13 and 14, and the laboratory analytical reports are provided in Appendix C.

### 5.6.6 Monitoring Well Hydraulic and Tracer Testing

The conventional monitoring wells were also utilized for hydraulic testing (i.e., slug tests) and tracer testing, providing K values and groundwater flux estimates that were compared to results obtained using other methods. SWTTs and slug tests were completed at five of the conventional monitoring wells. Falling and rising head tests were conducted in new monitoring wells by inducing a near instantaneous head change using a solid slug of known volume, then monitoring recovery with the pressure transducers. The data were analyzed to estimate K using AQTESOLV (www.aqtesove.com). The monitoring well slug testing results are provided in Appendix D.

SWTT methods are well developed for conventional vertical borings and wells (Drost et al. 1968; Gaspar and Oncescu 1972; Grisak et al. 1977; Hall 1993) and generally consist of replacing the water column in a well or borehole with a tracer solution without imposing an artificial head in the aquifer, and then measuring the subsequent decline of tracer concentration in the well. The observed rate of tracer concentration decrease, or washout, is then interpreted using analytical models to calculate the local groundwater flux and velocity. SWTTs provide a relatively simple, fast, and cost-effective alternative to multiwell tracer tests. However, it is important to note that an SWTT will not provide data to allow determination of groundwater flow direction. A variety of tracers can be used, including fluorescent tracers, anionic halides (e.g., chloride, bromide), and heat. For this project, a salt (sodium chloride) tracer solution was used to achieve the target specific conductivity contrast of approximately 500 microSiemens per centimeter greater than baseline conditions. Alternatively, distilled water can be used to create a reduction in specific conductivity that can be used as a tracer signal.

### 5.6.7 Water Level Measurements

Depth to groundwater was measured in the MLS and conventional monitoring wells, prior to each sampling event. The water level meter was decontaminated prior to initial use and after each subsequent use. Hydraulic head data from the MLS and nested wells also informed hydraulic gradients used in groundwater and contaminant flux estimates from VWS datasets and from vertical datasets (e.g., with the K estimates from grain-size analyses for groundwater flux). An Excel-based tool (HydrogeoEstimatorXL) was employed for the gradient magnitude and direction estimates (Devlin and Schillig 2017). The MLS has two ports that are co-located with the horizontal VWS ports (i.e., spanning the same depth intervals and positioned laterally at the mid-way position of the horizontal port) and the additional vertical information allowed quantification of uncertainty in flux estimates from the horizontal VWS installations.

Data logging pressure transducers were deployed in three monitoring wells. This included MW-VRTB-03S along the VWS transect and upgradient and downgradient wells MW-VRTB-01S and MW-VRTB-02S along the VWS longsect at the same elevation. These locations allowed triangulation to assess changes in horizontal hydraulic gradients during the project monitoring period, which were applied in groundwater and contaminant mass flux/discharge estimates. High-resolution water level and temperature data were transmitted for evaluation via a cellular service. Groundwater elevations were calculated using the surveyed top of casing elevations. An evaluation of hydraulic gradient patterns is provided in Appendix J.

### 5.6.8 Purge Water Waste Management

Liquid waste was generated while sampling the VWSs and vertical monitoring wells during the eight monitoring events conducted after installation of the VWSs. Groundwater purged during sampling, as well as water used for decontamination purposes, was surface spread on site.

# 6.0 DATA ANALYSIS AND FLUX METHODS

A variety of data analysis techniques and statistical methods were used to evaluate the data collected as part of this project, to support assessment of the performance objectives. Data analysis techniques are presented throughout this section, followed by an assessment of each individual performance objective in Section 7.

## 6.1 CONTAMINANT MASS FLUX/DISCHARGE

The hydraulic and concentration data developed through the pre-design characterization activity and performance monitoring were used to estimate groundwater flux and contaminant mass flux/ discharge. Groundwater and contaminant flux are referred to as measurements per unit cross-section area, whereas discharge refers to the integrated values across the entire control plane of interest, ideally covering the entire plume zone. As described by the ITRC (2010) and elsewhere, mass flux/discharge is generally estimated using three general approaches: transect methods, well capture/integral pump test methods, and passive flux meter methods. Comparisons between the different contaminant flux/discharge methods have been presented by Goltz et al. (2007), Beland-Pelletier et al. (2011), and others. The transect methods approach is where horizontal VWSs are mostly applicable for contaminant mass flux/discharge estimation and is further discussed below.

Transect methods (e.g., Guilbeault et al. 2005; Einarson et al. 2010) were applied, in which individual monitoring points are used to estimate groundwater flux and measure groundwater contaminant concentrations. These individual measurements are integrated over the transect area to estimate the total groundwater discharge and contaminant mass discharge, $M_D$, using:

$$M_D = \sum_{i=1}^{N} C_i q_i A_i \qquad \text{(Equation 1)}$$

Where:

$C_i$ is the contaminant groundwater concentration

$q_i$ is the groundwater flux attributed to the element area $A_i$.

Groundwater flux, $q_i$, can be estimated using:

$$q_i = K_i \, x \, i \qquad \text{(Equation 2)}$$

Where:

$K_i$ is the hydraulic conductivity

$i$ is the hydraulic gradient.

A key factor in the use of transects is appropriate spatial resolution (i.e., data density) to adequately define the groundwater and contaminant distributions, in light of the typical large heterogeneity that can occur in unconsolidated sedimentary systems, particularly in the vertical direction, and the commensurate large variability in plume contaminant concentrations, which can also vary by orders of magnitude over short vertical distances. For example, based on detailed transect evaluations at three chlorinated solvent contaminated sites, Guilbeault at al. (2005) showed that orders of magnitude variations in concentrations occurred in vertical distances of 0.10 to 0.30 meter.

At the three sites, as much as 75% of the total mass discharge occurs within 5 to 10% of the plume cross-sectional area, with sampling frequency as tight as 0.10 to 0.30 meter in the vertical direction and a few meters apart in the horizontal direction. In this approach, $q_i$ was estimated indirectly via measurements of K (e.g., via slug tests, short term pump tests, estimates based on lithology or grain size analyses; Cormican et al. 2020) and inferred from HPT data (e.g., McCall and Christy 2020). Hydraulic gradient values ($i$) were estimated from the local groundwater monitoring network (Devlin and Schillig 2017) and is generally the parameter exhibiting the least variability compared to K and contaminant concentration variability. Data from point dilution tracer tests and the A-DTS were also used for direct measures of $q$ values.

Groundwater flux was estimated by multiplying K by the measured site hydraulic gradient, and contaminant mass flux was calculated by multiplying the groundwater flux by the contaminant concentration measured in groundwater samples from each interval. Contaminant mass discharge across a transect can then be assessed by summing the contaminant mass flux for each sampling interval multiplied by its respective representative area (Equation 1). Insights from the vertical characterization can be used to constrain the vertical dimensions applied in the representative area estimates.

The polygon method applied in a simple spreadsheet was used for interpretation of VWS transect data. For EVS-based analysis kriging-based geostatistical methods were used to interpolate the contaminant and K distributions, and to integrate these over transect areas to estimate mass discharge (with user inputs including control points and others to ensure reasonableness). Summation of nodal data from the mass flux model was used to estimate the total mass discharge along transects. The analysis assumes an equidistant grid cell spacing in the model, transects that are perpendicular to groundwater flow, and an average hydraulic gradient from available groundwater elevation measurements.

One performance objective that was assessed during the data analysis and mass flux/discharge comparisons was determining how to achieve optimal placement of the horizontal ports along transect(s), which were guided using high-resolution vertical datasets. Specifically, the focus was on:

- Understanding the necessary data density, given the typical high spatial variability of K and contaminant concentrations within plumes.
- Limitations of installing horizontal systems at different depth intervals across a plume, where two to three systems installed at different depth horizons along a transect may be a practical limit.

High-resolution permeability data collected with HPT and the concentration data collected with VAP borings were evaluated in 3-D using EVS software to facilitate mass flux evaluation. Once assembled in a 3-D model, the interpolated data fields for conductivity and concentration are multiplied together, along with horizontal groundwater gradient, to produce a spatial distribution map that shows an estimate of mass flux on two-dimensional cross sections. This approach provides insight to mass movement, plume maturity, and plume morphology, and allows for future evaluation of remedy approach, location, and design.

In addition to mass flux applications, the EVS model was used for mass discharge estimates. Nodal data from the EVS mass flux model can be summed to estimate a total mass discharge along each transect. Comparison of new transects and estimated mass flux/mass discharge were compared to mass flux/mass discharge estimates from the 2019 ESTCP investigation. Computations in EVS were also used to evaluate minimum data requirements for designing a VWS as described by Performance Objective 4 in Section 7.4.

Every method has inherent biases, limitations, investigation scale and assumptions and no dataset can completely describe the field conditions. The error and uncertainty of the datasets were evaluated by varying assumed parameters, analysis models, examining temporal variability, and examining detection limits (both lower and upper). This step demonstrates how error or uncertainty are propagated and how individual parameter uncertainty contributes to overall uncertainty in flux estimates (Taylor 1997).

## 6.2 TEMPORAL VARIABILITY

Temporal variability of hydraulic gradients and contaminant concentrations were evaluated through time using repeated monitoring of existing wells, MLS, and VWSs. Care was taken to understand any trends that may result due to changes in natural and anthropogenic conditions and, in particular, time-series analysis techniques will target seasonal and operational changes.

For the data evaluations, the zone along Transect 2 within which overlapping vertical characterization data (from prior investigations in 2019 and 2021) with the VWS installations is referred to here as the Transect Control Plane. The only datasets with sufficient spatial coverage to integrate groundwater and contaminant fluxes crossing this plane, using the methodology described in Section 8.1 of the Demonstration Plan (Divine et al. 2021c), will be:

- Horizontal VWS installations spanning the control plane, with two systems at different elevations, each having eight port intervals, and with hydraulic testing providing K estimates from each port interval and groundwater sampling data providing contaminant concentrations.

- Vertical HPT/VAP datasets providing estimated K and discrete concentration data from nine locations across the control plane (six conducted in 2019, three completed in 2021). Each location will have continuous HPT profiles (providing continuous K estimates) and between 5 to 7 depth zones of VAP sampling using an approximately 4-foot-long screened interval providing contaminant concentrations throughout this interval. K estimates from pneumatic slug tests (PSTs) will also be obtained from all 2021 VAP sampling zones along the transect. Horizontal hydraulic gradients from the existing wells and new monitoring infrastructure (including paired vertical wells to be instrumented with transducers, and the 7-port CMT multilevel system) will also be applied in these flux estimates.

The comparison between flux estimates using VWSs and the vertical HPT/VAP dataset provides a basis for evaluation of the accuracy of the VWS assessment for flux assessment for PFAS/PFOS contamination. This is for a scenario where the vertical positioning of the VWS screens were informed by higher resolution vertical profiles, therefore having the greatest chance of successfully delineating groundwater and contaminant flux. Given the high spatial variability expected for the K and contaminant distributions, neither method was expected to produce a perfect result.

The vertical profile datasets should produce a more accurate result given the higher spatial coverage of datapoints. Within the control plane, there will be 16 VWS sample intervals (at two depths) and approximately 50 to 60 VAP sample intervals (five to seven depths; nine locations). Temporal variability in plume concentrations will affect the VAP sample interpretations given the more than 2.5-year time difference between the 2019 and 2021 sampling events. Temporal sampling of the CMT MLS installed as part of this project provided additional insights into the plume temporal variability across the sampling events.

## 6.3 UNCERTAINTY AND BIAS

Beyond the direct comparisons indicated above using the sampling zone estimated K, contaminant concentrations and hydraulic gradients to estimate integrated groundwater and contaminant fluxes across the control plane, further analyses were conducted to estimate the possible uncertainty and bias in these flux estimates. Every method has inherent biases, limitations and assumptions (i.e., there is no correct or ideal dataset to compare against as a standard). For vertical installations, HPT estimated K can be uncertain and influenced by operational conditions, geological conditions, varying probe advance rates, and other things. The 2021 locations along the transect/control plane allowed comparisons of K datasets and groundwater flux profiles at the three locations using:

- HPT estimated K and horizontal hydraulic gradients from monitoring wells
- K estimated at the VAP sample locations and horizontal hydraulic gradients from wells
- K estimated from core samples (grain size/permeameter) with higher resolution at the middle CMT well location and horizontal hydraulic gradients from monitoring wells
- K estimated from slug tests and horizontal hydraulic gradients from monitoring wells
- Groundwater flux from vertical stand-alone fiber optic installations and A-DTS testing.

For the VWS installations, besides hydraulic testing providing K estimates, which were combined with horizontal hydraulic gradient estimates for groundwater flux estimates and integrated across the control plane, horizontal flux profiles were also measured using the A-DTS (deployment of fiber optic cable paired with one of the VWSs, as well as a stand-alone fiber optic cable a short distance away at the same depth interval) for comparison. Tracer tests were also used to assess groundwater flux.

For contaminant flux, groundwater concentrations are combined with the groundwater flux data to estimate contaminant mass fluxes. Differences in contaminant concentrations can be accessed via comparison of different resolution measurements conducted during this study. For example, the VWS spatial coverage is limited in the vertical dimension and could easily miss higher concentration zones, which was assessed by comparison with the higher resolution vertical profiles, including those collected from VAP, CMT multilevel sampling, and from the golden spike high-resolution soil core sampling (Figure 30, below). Integration of the groundwater flux and contaminant flux along profiles at the three locations where the multiple higher resolution vertical datasets were collected, and which overlap with VWS screens, provided a basis for evaluation of the uncertainty of the VWS flux estimates. In summary, while some uncertainties are irreducible and difficult to rigorously quantify, their general significance can be assessed through a redundancy of data, data types, and multiple analysis methods. Overall, the uncertainties in these analyses are considered acceptable for the purposes of this demonstration.

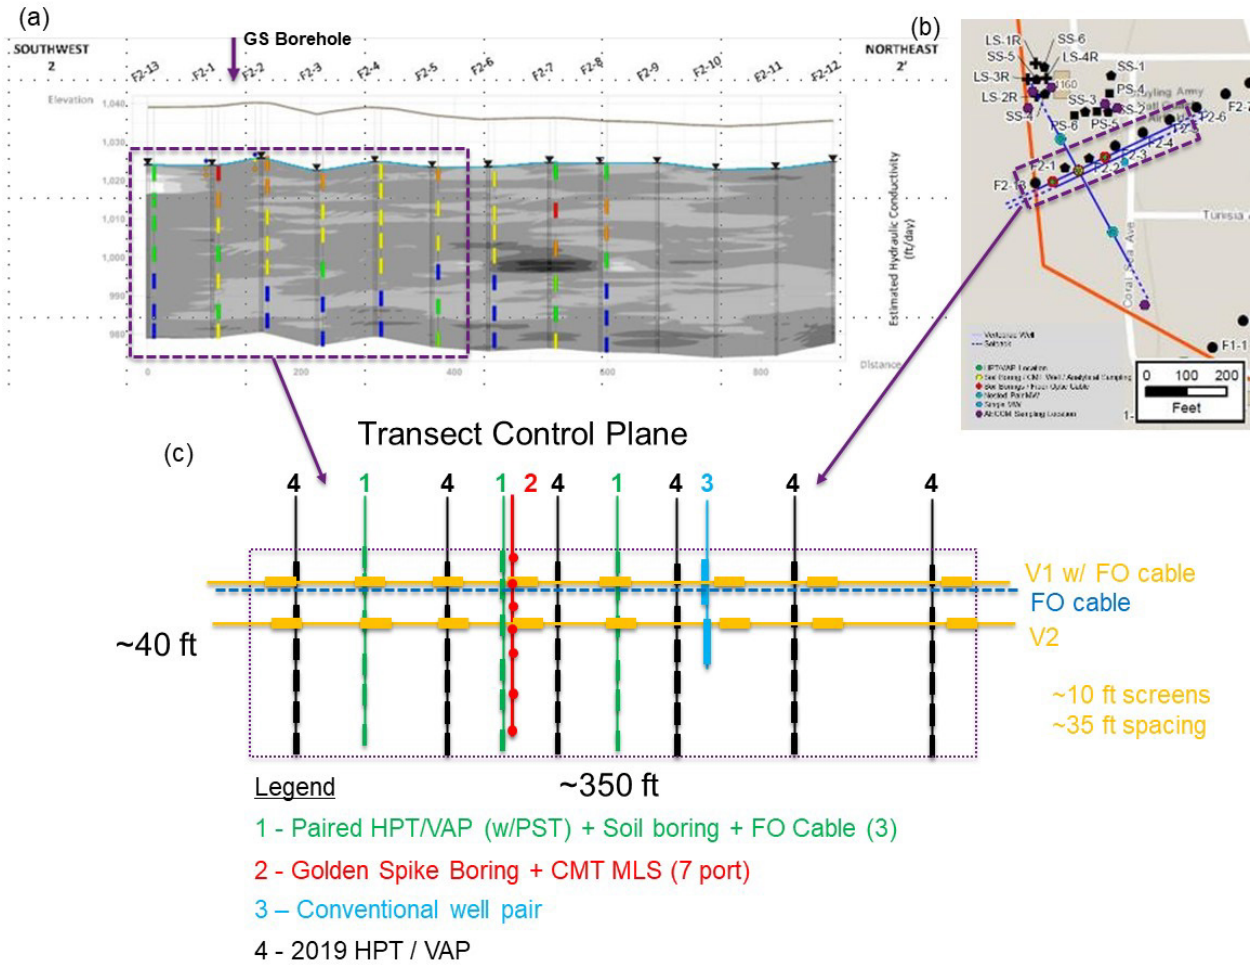

**Figure 30. VWS Data Plots**

*(a) Conditions along Transect 2 showing HPT estimated K and VAP total PFOS concentrations (color coded) from 2019 investigations, (b) Plan view map of the 2019 and 2021 locations, and orientations of the VWSs, and (c) Transect control plane, which we refer to as the interval along the transect where overlapping datasets were collected from the VWS installations and vertical data collection points (2019 and 2021). This highlights conceptually the various datasets collected and used for the groundwater and contaminant flux estimates and to assess the performance/ uncertainty of these estimates from the horizontal VWSs versus the vertical characterization data.*

# 7.0 PERFORMANCE ASSESSMENT

The data collected as part of this project were evaluated to determine if the success criteria for specific quantitative and qualitative performance objectives presented in Table 1 were achieved. This section discusses the assessment of each performance objective.

## 7.1 QUANTITATIVE PERFORMANCE OBJECTIVE 1: ACCURATE AND RELIABLE PLACEMENT OF SCREENS IN SUBSURFACE

This performance objective is intended to:

- Assess the reliability of bore-path navigation data for documenting as-built completion.
- Verify that the VWS can be successfully installed at planned target depth intervals.

### 7.1.1 Data Collected

The following data were collected to evaluate accurate and reliable placement of the VWS screens:

- Prior to directional drilling operations (September 2021):
  - The target bore paths were professionally surveyed and staked. The positions of the survey markers were provided in State Plane coordinates and the elevations were referenced to feet above mean sea level.
- During directional drilling (October 2021):
  - A walkover locating system was used to track the position of the drill head. The position of the drill head was marked when an additional drill rod was added to the drill string (every 10 feet).
  - Distances between the drill head and the pre-surveyed stakes were measured to determine the horizontal deviation from the planned bore path.
  - The depth of the drill head was also painted on the ground beside the rod marking (Figure 31, below).

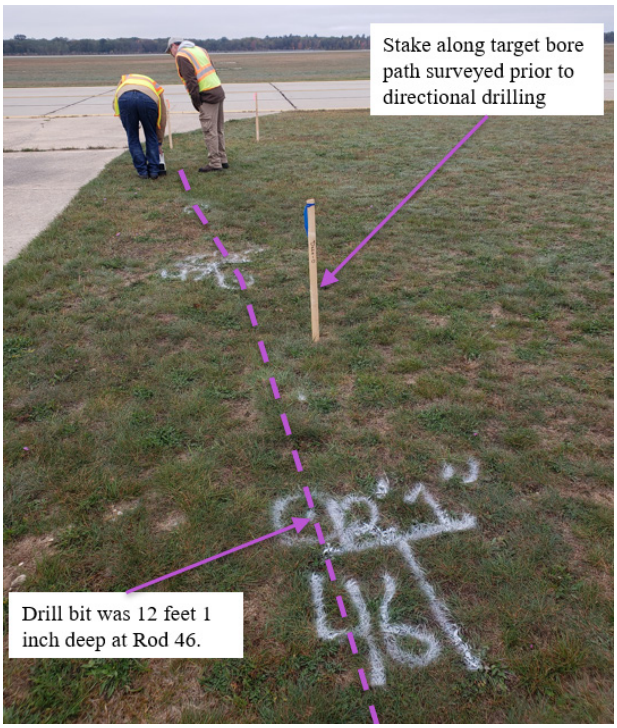

**Figure 31. Directional Drilling Navigation**

- After installation of the VWSs (August 2022):
  - A total of 19 as-built points along the shallow and deep transects were re-marked. This included the east end of all 16 screens plus the west end of three of the screens. Both ends of the three screens were surveyed because they are within the curved portion of the bore and there is a slope from one end of the screen to the other.
  - The locations of the screens at the shallow and deep transects were determined using RF inductive line tracing with a multifrequency transmitter and receiver. The RF line tracing involves connecting the multifrequency transmitter to a high-strength copper clad tracing wire that was bundled with the VWSs during installation, applying a frequency specific signal to the tracing wire, locating the dedicated frequency at specified intervals along the wells, and recording the depth determined by the receiver.

This resulted in three sets of coordinates for comparison:

1. Planned coordinates
2. As-built coordinates from the drilling navigation system
3. As-built coordinates from inductive line tracing.

The coordinates were then used to calculate vertical differences for comparison to the success criteria.

### 7.1.2 Data Interpretation

Success is considered achieved if:

- At least 80% of all drilling navigation data agree within 1.5 feet (elevation) of the bore path elevation determined by geophysical survey.
- Eighty percent of the as-built data agree within 1.5 feet of the planned target depth elevations.

The goal was to install the VWS within 1 foot of the planned target depth. However, there are inherent limitations in the accuracy of depth measurements collected during and after directional drilling. The two main factors (discussed further in the next paragraph) that affect depth accuracy are:

1. The borehole is reamed to a diameter approximately 50% larger than well materials.
2. The exact position of tracer wire is not consistent and can vary between top, bottom, and sides of well.

For these reasons, depth measurements during (drilling navigation data) and after VWS installation (geophysical methods) have an inherent irreducible uncertainty of +/- 0.5 foot. Therefore, the depth accuracy of +/- 0.5 foot was added to the goal of +/- 1 foot, resulting in the overall target tolerance limit of 1.5 feet.

Well diameter affects the accuracy of the depth measurements, with larger well diameters resulting in less accurate depth measurements. This is because of differences between the depths obtained during pilot bore drilling and the actual well installation depth. The borehole navigation data are obtained during pilot hole drilling, from a sonde behind the drill head. Then the borehole is reamed, typically to 50% larger than the well materials, followed by pulling the well into place. The final position of the well materials is at the bottom of the borehole, due to the weight of the drill pipe/ well materials and stresses imparted as the well materials are pulled through the curved sections of the borehole. This results in uncertainty between the depth measured during borehole navigation and the final depth of the well materials. In the case of the VWSs, the 4-inch-diameter pilot bore was reamed to a final diameter of 6 inches. Another factor that affected the accuracy measured using the RF is the location of the tracing wire on the VWS. The final position of the tracer line could be anywhere around the circumference of the well (top, middle, or bottom) depending on rotation of the well materials during pullback.

As presented in Table 24, below, the differences between the measurements were within the tolerance limit of + / - 1.5 feet for all six horizontal screens. When evaluating this performance objective, only the six shallow transect VWS screens along the horizontal section were considered (Figure 32, below). The two screens on the slopes (one at each end) of the shallow transect were omitted due to decreased accuracy of the walkover locating system when drilling at an angle from horizontal. When drilling at an angle, the three signals (front, back, and center sight) emitted by the sonde travel a longer distance to the receiver at the surface, which decreases the accuracy. A future recommendation (see Section 9) is to avoid placing screens on the sloped portion of the wellbore, due to decreased locating accuracy. In addition, the angled screen orientation increases the potential for grout intrusion into the screen, which is another reason to avoid installing screens at an angle.

***Based on the discussion above, the performance objective related to accurate and reliable placement of VWS screens in the subsurface is considered achieved.***

**Table 24. Comparison of Planned and Actual VWS Locations**

| Screen ID | Difference between HDD Navigation Data and Planned Target Depth (feet) | Difference Between HDD Navigation Data and Electromagnetic Line Tracing Depth (feet) |
|---|---|---|
| S-R7 | 0.32 | 0.08 |
| S-O6 | 0.19 | 0.25 |
| S-M5 | 0.20 | 1.42 |
| S-G4 | 0.10 | 1.00 |
| S-Y3 | 0.58 | 0.75 |
| S-S2 | 0.13 | 1.42 |
| % Agreement (less than 1.5 feet) | **100% (6 of 6)** | **100% (6 of 6)** |

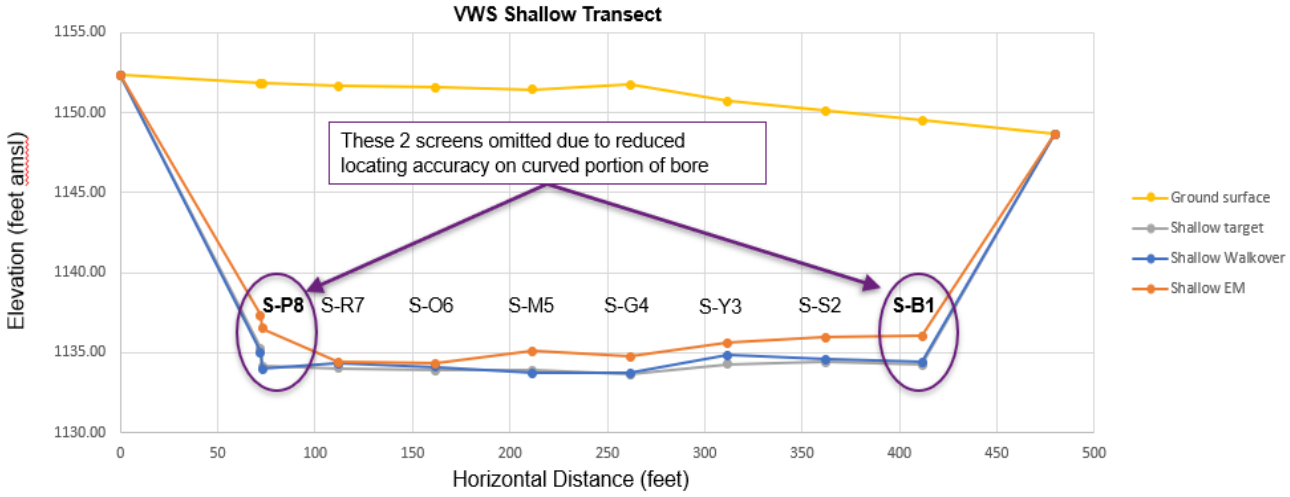

**Figure 32. Comparison of Planned VWS Screen Depths, As-Built Coordinates from the Drilling Navigation System, and As-Built Coordinates from Inductive Line Tracing**

## 7.2 QUANTITATIVE PERFORMANCE OBJECTIVE 2: VALIDATE METHODS FOR GROUNDWATER FLUX MEASUREMENT WITH VWSS

This performance objective is intended to assess the reliability and usefulness of several different methods for measuring groundwater flux across a VWS.

### 7.2.1 Data Collected

Groundwater flux across the transect was measured by multiple independent methods. The first method used K estimated from hydraulic tests completed during HPT activity prior to VWS installation. The measured K values at locations equivalent to the final VWS screen locations were used, and groundwater flux was calculated with the site average horizontal hydraulic gradient at the time of sampling, according to Darcy's Law. The second method was based on groundwater flux directly measured from SWTTs which is then used to determine representative K values for each screen segment. The third method used data from active fiber optic A-DTS. Because the DTS system was only installed along the shallow transect, the groundwater flux and flow calculations for each method are compared for only the shallow zone.

Another method that was evaluated was applicability of slug testing with VWSs. Slug testing was attempted using both inflow (falling head) and pneumatic slug testing methods. The inflow method involved inducing a known volume of water into the individual VWS segments. Pneumatic slug testing involved pressurizing the water column with air. It was concluded that skin effects were likely present, with slug testing results biased low and unreliable due to friction losses associated with the geotextile membrane used in the VWS construction. Therefore, VWS slug testing is not recommended or included in the following data interpretation.

### 7.2.2 Data Interpretation

Figure 33 (left), shows the average screen segment flows (average of eight monitoring events) for each of the primary comparison methods (HPT, SWTT, and A-DTS). Figure 33 (right) shows total transact calculated flow for each monitoring event. For comparison, this figure also shows average flows calculated using K-estimates based on size analyses from soil core samples ("Grain Size") and geostatistical-based (i.e., kriging) model of K-distribution based on all available K information at the site. The results based HPT data are notably lower than the other two methods for all segments and events. It is likely that for the GAAF, this is a biased-low method because the range for most K measurements at the GAAF (Figure 34, 30 to 300 ft/day) is near the approximate upper method limit for HPT testing (approximately 50 to 100 ft/day). Therefore, the HPT method is not considered reliable for the GAAF; however, it may be appropriate for sites with lower hydraulic conductivity.

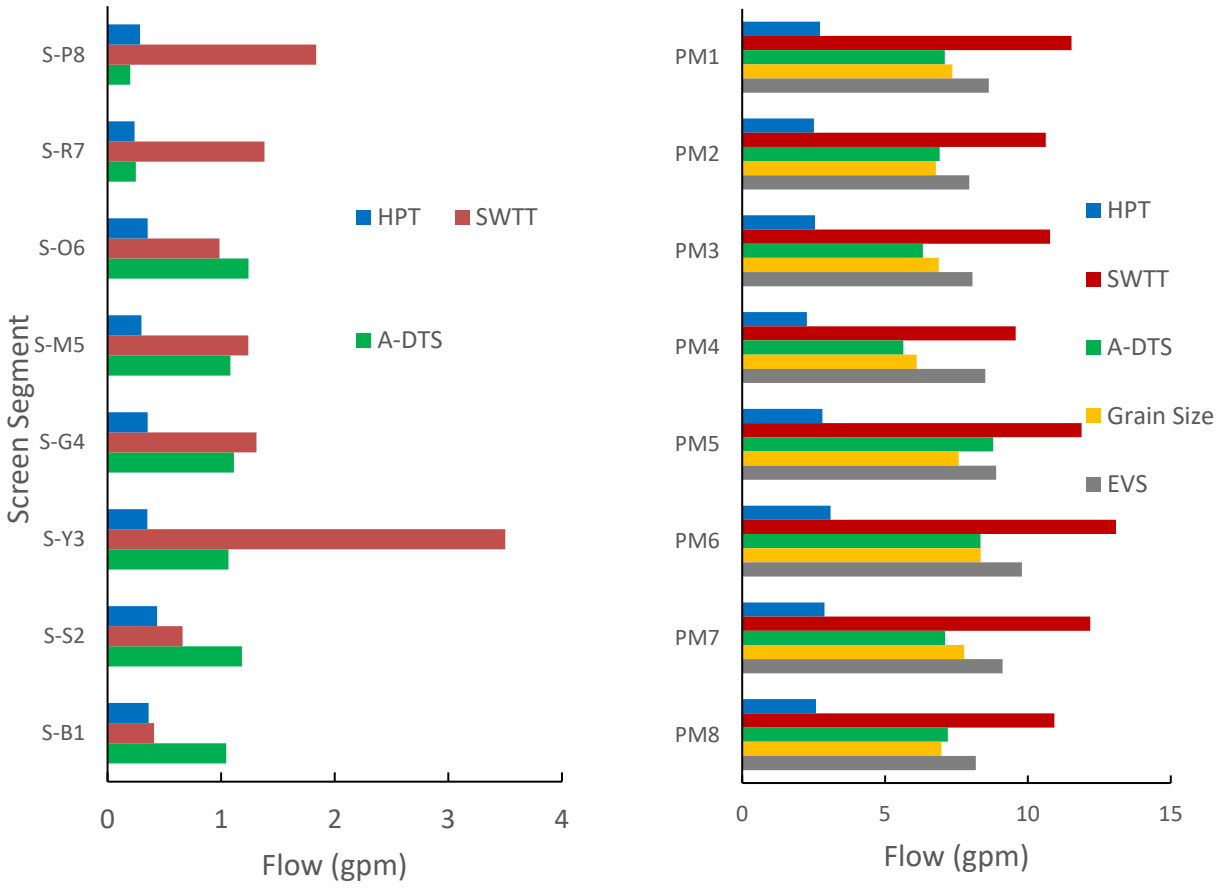

**Figure 33. Average Screen Segment Flows (left) for HPT, SWTT, and A-DTS, and Total Transact Calculated Flow for Each Performance Monitoring Event (PM1, PM2, etc.) for All Methods (right).**

The results for the DTS and SWT methods are similar for some screen segments and monitoring events, however, there are some screen segments where the SWTT method is up to twice as high as the DTS method. Based on the highly uniform K distribution at the site (Figure 34), it is unlikely that much higher permeability zones exist at those screens, and rather the SWTT method may be less reliable or biased high at these locations. In the Demonstration Plan (Divine et al. 2021c), it was proposed that success would be evaluated individually for each of the three methods and the performance objective would be considered to be achieved if:

- Repeated flux estimates for a specific method have an average relative percent difference (RPD) of <±25%.
- If through application of statistical analysis of variance, the result for a specific method agrees within 25% at an 80% confidence with the average of all methods.

If one method is determined to have failed, its result will be excluded from the average. For the relative standard deviation (RSD) for total transect flow across all eight monitoring events is similar, 14 and 10% for the DTS and SWTT methods, respectively. Because the HPT data are considered biased low, this second component of the success criteria cannot be evaluated as stated.

Generally, it is believed that some SWTT results for individual screens may be biased high because the low geologic heterogeneity would be expected to result in more uniform values across screen sections; however, conclusive data are not available requiring that the SWTT results be considered less reliable than the HPT results. Therefore, both methods are considered reliable and application of an averaging and complimentary approach likely results in the best estimate for the GAAF.

***Based on modified criteria, both the DTS and SWTT methods are considered to have achieved success for this performance objective.***

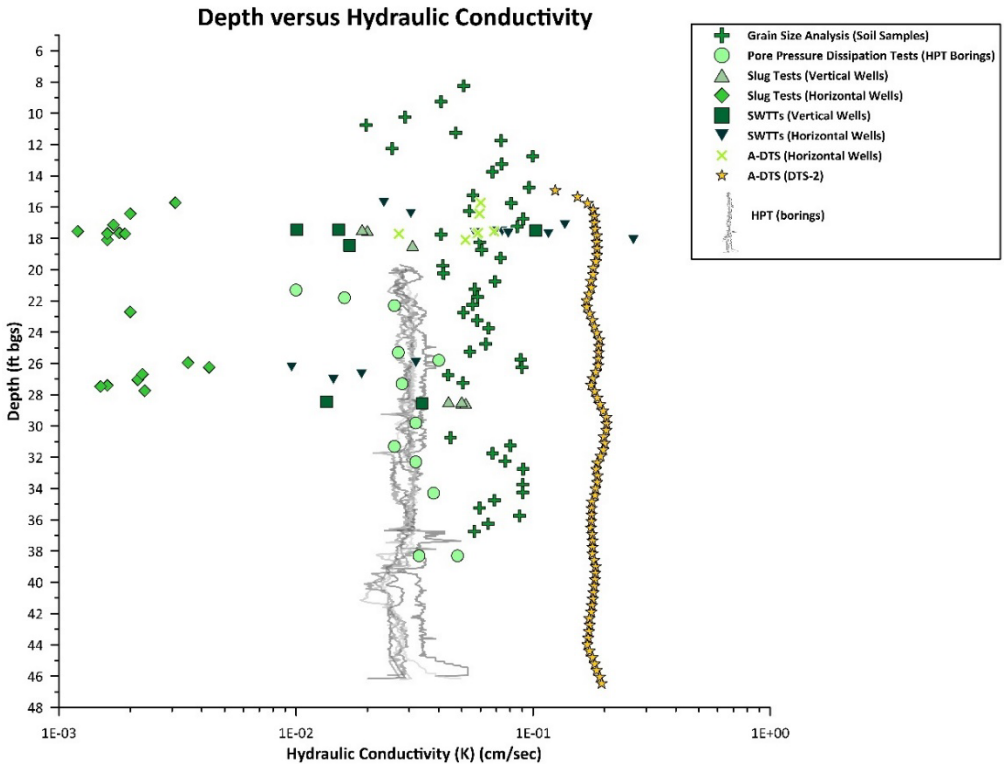

**Figure 34. Estimated K at the GAAF vs. Measurement Depth Comparing Multiple Methods**

*The majority of values fall between approximately 0.01 and 0.1 cm per second (30 and 300 ft/day).*

## 7.3 QUANTITATIVE PERFORMANCE OBJECTIVE 3: ASSESS COMPARABILITY OF SAMPLES COLLECTED FROM VWS SCREENS TO GRAB SAMPLES AND CONVENTIONAL MONITORING WELLS

This performance objective is intended to demonstrate that the groundwater samples collected from VWS screens are comparable to groundwater samples collected by conventional sampling methods commonly used in site characterization investigations, such as grab (e.g., VAP) samples obtained from direct-push drilling systems and samples from vertical monitoring wells. This performance objective was defined to confirm the overall representativeness of samples collected from the VWS and still accommodate irresolvable variances that may be the result of plume spatial variability caused by small-scale aquifer heterogeneity and flow system, and source variability and inherent differences in sampling methods.

### 7.3.1 Data Collected

Samples were collected quarterly from each individual screen in each VWS. These results were compared to nearby co-located groundwater samples from vertical borings and multilevel or conventional monitoring wells. These included one-time VAP grab samples collected as part of the prior ESTCP project at the GAAF (ER19-5203) and this ESTCP project. New multilevel and conventional wells installed during this project were also sampled multiple times. Sampling of these wells coincided sampling of the VWSs.

### 7.3.2 Data Interpretation

The high-resolution groundwater data generated from the previous ESTCP project at the site (completed in 2019) were evaluated to provide a basis for the success criteria for this performance objective. Numerous borings were installed previously, and VAP groundwater samples were collected from six to eight discrete intervals for each boring, generally between 15 and 50 feet below ground surface. Because the interval between 20 to 30 feet is the most important, the RSD of all samples collected from this interval was calculated for each boring. These results are shown in the left panel on Figure 35, below, and are plotted against the average concentration measured for the first year of quarterly monitoring. In general, RSD values range from less than 10% to more than 100% and appear to be independent of concentration magnitude. The average RSDs for PFOA and PFOS are 77 and 73%, respectively. Considering the uncertainty and limitations of the data, the average RPD for these data for the target interval is estimated to be 80%. This value was the basis for this performance objective.

The right panel of Figure 35, below, plots the RSD between samples from VWS and nearby VAP or vertical well samples. Figure 36, below, compares the average and range of samples collected from the VWS for the first four monitoring events to the closest VAP or vertical monitoring well. In general, sample results from the VWS are consistent with conventional sampling methods. The average RSDs for PFOA and PFOS are 59 and 62% (less than the goal of 80%), range from 1 to 182%, and appear to be independent of concentration magnitude.

***This comparison confirms the overall representativeness of samples collected from VWSs and the criteria for this performance objective are considered achieved.***

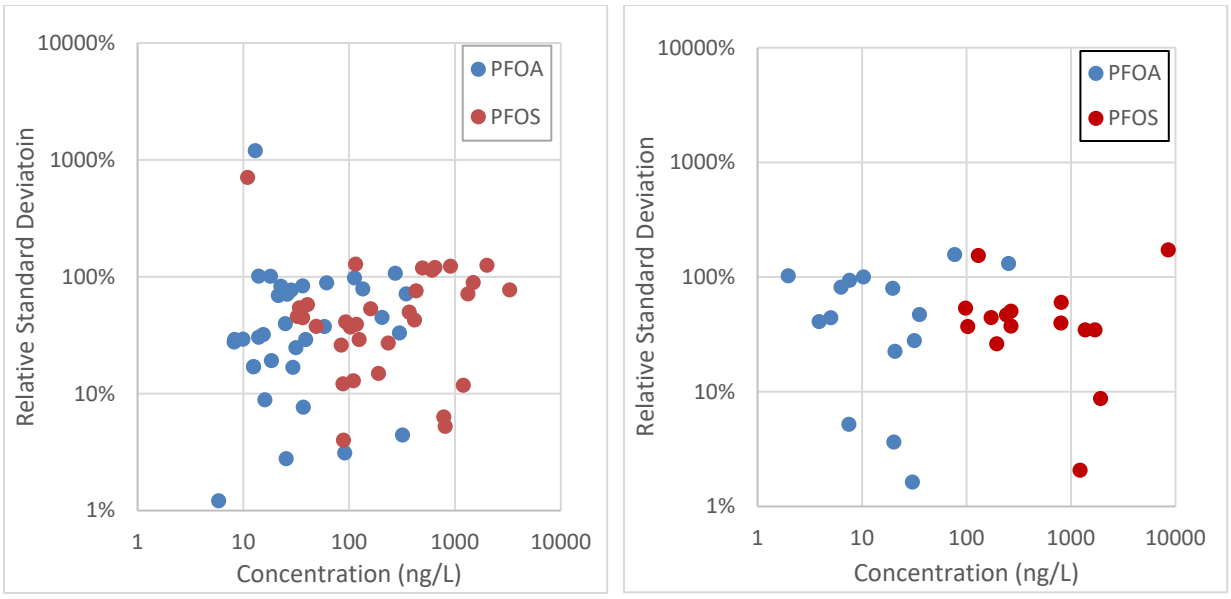

**Figure 35. RSD of all Groundwater Samples from the 20- to 30-foot Depth Interval**

*Left: RSD of previously collected groundwater grab samples to samples from the VWSs. Each point represents the results from one boring and is a measure of the variability of concentrations in the interval between 20 and 30 feet. Right: RSD between samples from VWS and nearby VAP or vertical well samples.*

*Specific VWS screen identification names are noted on the x-axis.*

## 7.4 QUANTITATIVE PERFORMANCE OBJECTIVE 4: DEMONSTRATE METHOD TO IDENTIFY APPROPRIATE MASS FLUX ZONES TO TARGET VWS SCREEN PLACEMENT

Development of a low-cost screening method and/or a priori sampling data to identify target mass flux zones is critical to cost-effectively deploy the horizontal VWS transect or longsect wells to obtain maximum resolution and derive accurate mass discharge information. This performance objective is intended to assess the practical and cost-effective use of prior site information and pre-design vertical characterization data to design a VWS that is optimally placed and will yield reliable contaminant mass flux/discharge information.

### 7.4.1 Data Collected

Data used to support the assessment of this performance objective included all previously existing HPT and VAP groundwater grab sample concentration data as well as additional high-resolution data collected during the pre-design investigation (see Section 5.2). These data were incorporated into the existing 3-D site model (EVS model) used in a complimentary effort to design the placement locations of the VWSs (Figure 37). The VWSs were designed to yield mass discharge estimates that agree with the results from the EVS model which includes all other available site data. This evaluation is specifically considered in Performance Objective 5.

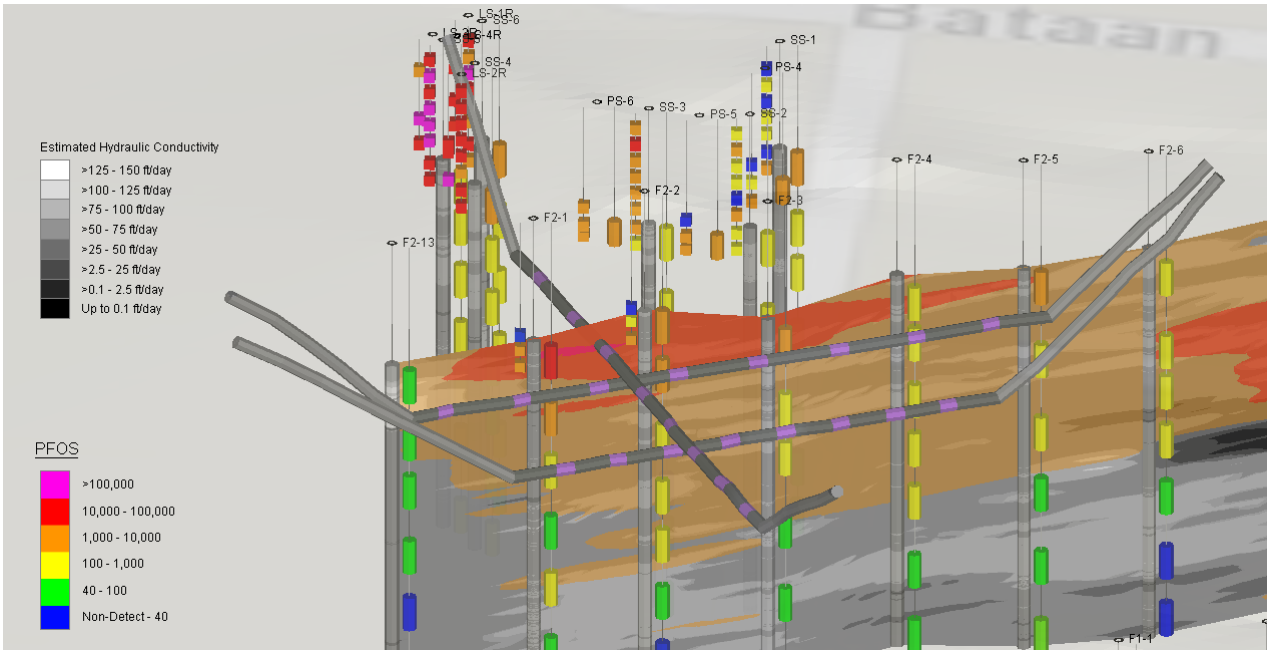

**Figure 37. 3-D Model Showing Design of the VWSs Based on Available Data. Hydraulic conductivity values are ft/day and PFOS concentrations values are ng/L.**

### 7.4.2 Data Interpretation

To understand the amount of pre-design data necessary to support a reliable design, a bootstrapping-type exercise was performed. PFOS mass discharge was calculated using all site data (i.e., 100% of data) and then some data were sequentially removed and PFOS mass discharge was recalculated.

The predicted mass discharge values from these alternate designs were calculated and compared. These results are shown in Figure 38. The y-axis represents the calculated PFOS mass discharge values for each model normalized to the value from the 100% model. This is a practical approach whereby a relationship between the amount of pre-design data available and the predicted mass discharge measured from the resulting VWS design can be developed. As seen in Figure 38, similar PFOS mass discharge values are estimated when 100, 90, 80, and 60% of all available data were used. More significant variation is observed when 40 and 20% of the data are used. This implies that more than enough pre-design data were available to support the VWS design. This performance objective is considered partially achieved because a clear relationship between data used and the calculated mass discharge was developed via a practical method. However, the analysis did not yield results that agreed within ±25% of the mass discharge estimated independently from the other available site data (e.g., on Figure 38, below, calculated relative mass discharge values between 0.75 and 1.25). The average results from the HPT, DTS, and SWTT methods yielded results of 1.4, 1.6, and 6 respectively. However, as discussed further in Performance Objective 5, the ±25% target is likely overly and unnecessarily optimistic given the geologic complexities and concentration variability. As such, this performance objective may still be considered achieved.

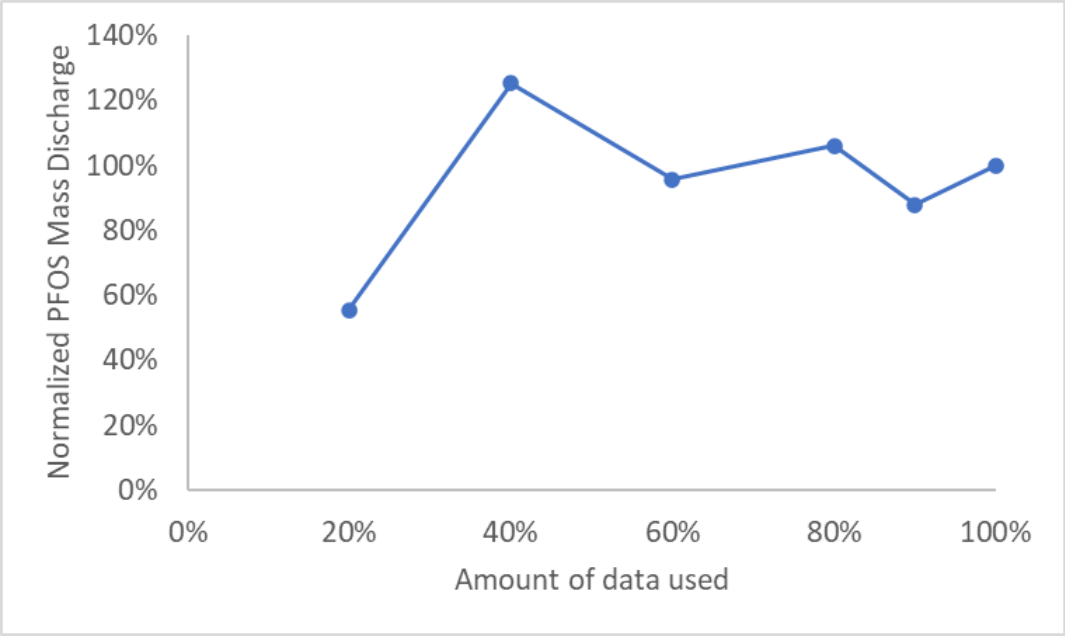

**Figure 38. Relationship between the Amount of Available Data used and Calculated PFOS Mass Discharge**

## 7.5 QUANTITATIVE PERFORMANCE OBJECTIVE 5: VALIDATE VWS APPLICATION FOR QUANTIFYING MASS FLUX/DISCHARGE ALONG TRANSECTS

This performance objective is intended to verify the reliability of using VWS transects to measure PFAS mass flux/discharge.

### 7.5.1 Data Collected

Mass flux/discharge normal to groundwater flow were calculated for the transect VWSs using groundwater samples collected from VWS well screens and the different measures of Darcy flux attributed to each of the screen zones (hydraulic testing, point-dilution tracer testing, A-DTS). These estimates were compared to mass discharges estimates developed from geostatistical modeling of hydraulic conductivity data from conventional vertical borings/wells installed along the same transect (most of these data were developed under prior ESTCP project ER19-5203 and were supplemented with new data collection) and PFAS concentrations measured in VWSs for each performance monitoring event. These analyses were completed in EVS and an example of the calculated PFOS mass flux distribution is shown on Figure 39, below (the hydraulic conductivity field is depicted in greyscale and the mass discharge distribution is depicted in color flood with the high values corresponding to warmer colors).

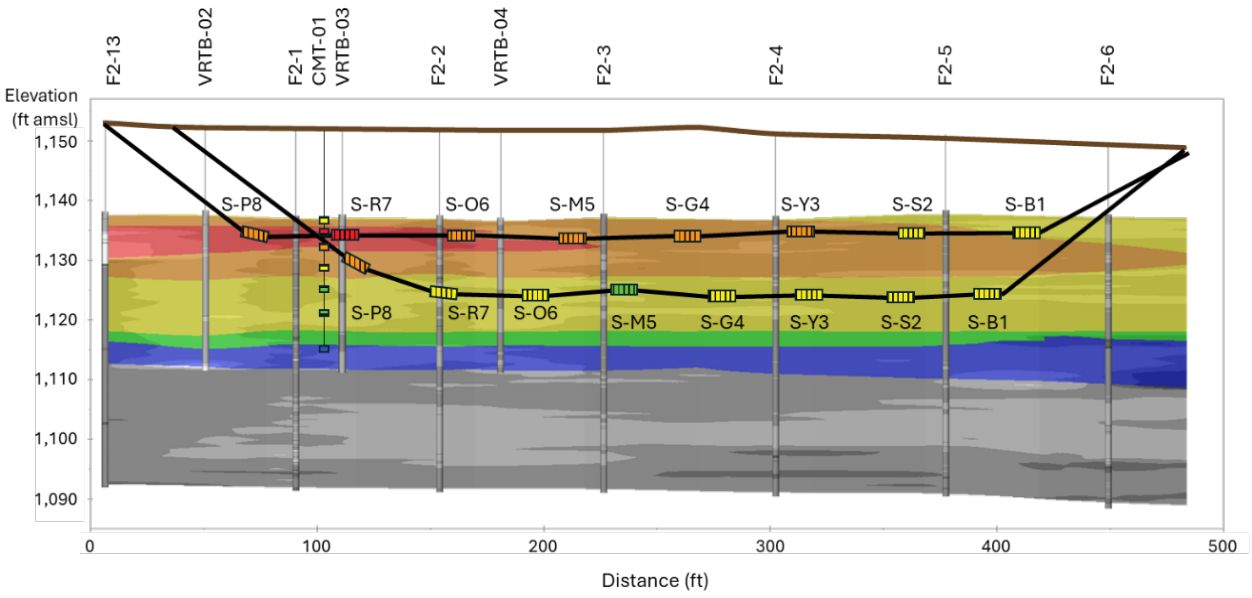

**Figure 39. Example EVS Calculated PFAS Mass Flux Distribution for Performance Monitoring Event #2**

### 7.5.2 Data Interpretation

The PFOS mass discharge estimates for each method and for each monitoring event are presented in Table 25, with average values ranging for the shallow-only transect from 58 to 326 mg/day (0.21 to 0.12 kg/year). In the Demonstration Plan (Divine et al. 2021c), it was proposed that success would be considered achieved if mass discharge estimates with VWSs agree with the conventional approach (using all data, including vertical borings/wells, in a geostatistical model [i.e. EVS])) within 25% at an 80% confidence.

**Table 25. Comparison of PFOS Mass Discharge (mg/day) for All Performance Monitoring Events.**

| Method | PM1 | PM2 | PM3 | PM4 | PM5 | PM6 | PM7 | PM8 | Average | RSD |
|---|---|---|---|---|---|---|---|---|---|---|
| **EVS** | 38 | 35 | 41 | 40 | 130 | 109 | 70 | 56 | 65 | 56% |
| **Grain Size** | 135 | 125 | 116 | 144 | 181 | 210 | 179 | 168 | 157 | 21% |
| **DTS** | 69 | 56 | 56 | 46 | 142 | 147 | 100 | 113 | 91 | 44% |
| **HPT** | 50 | 46 | 43 | 54 | 67 | 78 | 66 | 62 | 58 | 20% |
| **SWTT** | 279 | 257 | 238 | 309 | 382 | 431 | 367 | 344 | 326 | 20% |

Based on the first eight performance monitoring events, none of the methods meet this statistical level, and consequently, the criteria for this performance objective cannot be considered achieved as originally stated. However, given the complexity of subsurface characterization and PFAS transport, this may have been an unrealistic success criterion.

Although the EVS-based method utilizes the most site geological data it should not necessarily be considered the "gold standard" since its results are highly dependent on geostatistical parameter values and associated data interpolation. This method consistently yielded some of the lowest values, suggesting some other methods (especially SWTT) may provide estimates with a high bias. Regardless, the average results for both the HPT and A-DTS agree with the EVS result within a factor of 2, and all methods fall within a factor of 3 agreement envelope (see Figure 40). Furthermore, the event-to-event variability, as measured by the relative standard deviation (RSD) is similar for all of the methods (with EVS being the highest), ranging from 20 to 56%. This implies that the differences in methods are related more toward a systemic consistent bias rather than precision and repeatability. In practice, remediation decisions are not made from specific mass discharge values or single estimates, but rather from trends in mass discharge over time. As such, all methods appear to be reliable for this application. In most cases estimating mass discharge from several methods will increase confidence in estimated values and provide insight regarding uncertainty of the estimates. Overall, the results support the use of VWS for PFAS mass discharge estimation by multiple independent methods.

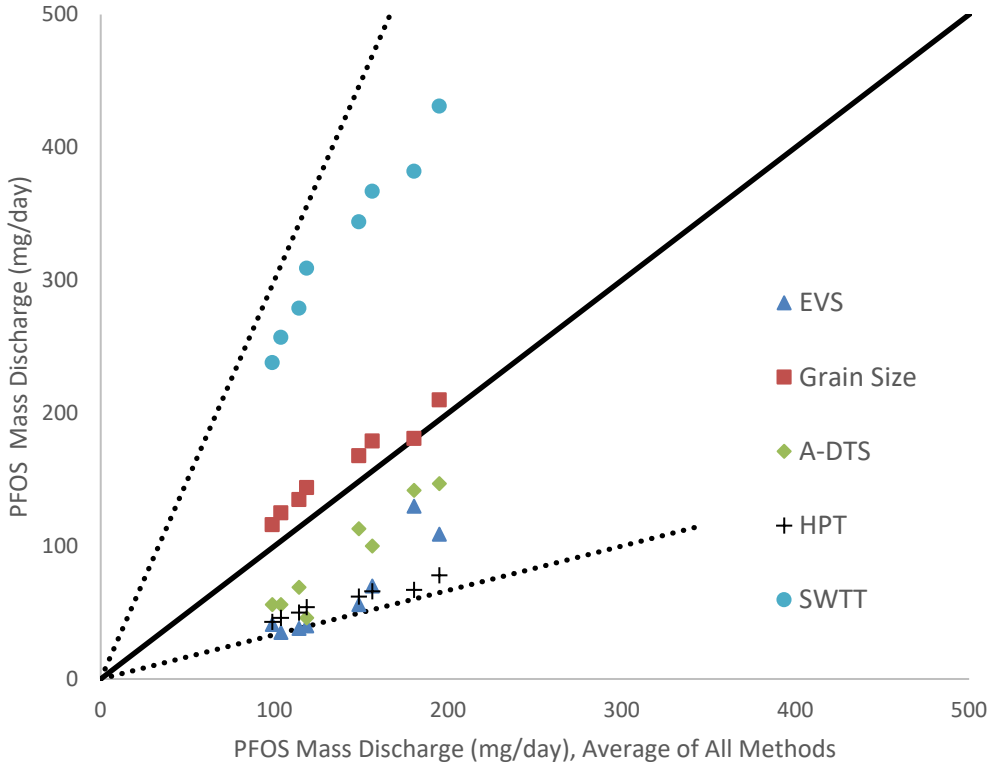

**Figure 40. Comparison of PFOS Mass Discharge Estimates for Each Performance Monitoring Event to the Average of All Methods for Each performance Monitoring Event.**

*The solid line represents 1:1 correlation and the dotted lines represent an agreement envelope of a factor of 3.*

## 7.6 QUANTITATIVE PERFORMANCE OBJECTIVE 6: VERIFY MATERIAL COMPATIBILITY WITH PER- AND POLYFLUOROALKYL SUBSTANCES

This performance objective is intended to demonstrate that the materials used in a VWS will not meaningfully affect measured PFAS concentrations in groundwater samples collected from a VWS. Other researchers (Denly et al. 2019; Rodowa et al. 2020) have evaluated the potential for cross-contaminant and positive sampling bias in a wide range of materials associated with groundwater sampling. These researchers have generally concluded that although Teflon™-containing materials (i.e., polytetrafluoroethylene) should be avoided, there is little contamination risk from most common materials including silicon, PVC, and low- and high-density polyethylene. This performance objective verified the expectation of PFAS compatibility based on previous published work and assessed the key components of the Vertebrate™ system that are in direct contact with sampled water.

### 7.6.1 Data Collected

As discussed in Section 5.3, laboratory-based experiments were completed and focused on key VWS components including the sock polyester geotextile screen wrap, HDPE screen, and HDPE riser tubing. Specifically, rinsate experiments (passing clean water over system components to document

no significant PFAS leaching) and soaking experiments (soaking key system components in a known PFAS solution to document no significant PFAS mass loss) were completed. The laboratory analytical results are summarized below.

During positive bias testing, only very low levels of PFOA (0.97 ng/L; this value is between the laboratory method detection limit and the laboratory practical quantitation limit) were detected in the rinsate sample from the geotextile screen wrap. This concentration is below the MCL of 4.0 ng/L for PFOA. PFAS was not detected in rinsate from any other system components. This very minor detect is not expected to meaningfully affect groundwater results at most sites. Nevertheless, another sample of geotextile was pre-washed with methanol and then solid phase laboratory analysis was then performed on the geotextile. No PFAS compounds were detected. Therefore, a simple methanol-based washing step can be implemented for the geotextile screen materials prior to use at PFAS sites.

A second set of tests were conducted to indirectly measure the potential for PFAS sorption to VWS well materials to affect sample results (i.e., cause a negative bias). The geotextile was soaked for 72 hours in a spike solution with very high PFAS concentrations (1,000 µg/L for all PFAS compounds analyzed). This is considered a reasonable soaking time because in common field settings, fresh groundwater is constantly entering the well and only remains in contact with the well materials for a few hours or days. The geotextile was then rinsed three times in deionized water and then analyzed for PFAS by solid phase analysis with methanol extraction, which is assumed to have recovered all PFAS mass that may have sorbed to the geotextile. Only three PFAS compounds were detected at low concentrations after the aggressive methanol extraction (Table 26). These results confirm some PFAS compounds did sorb to the well materials, however, the detections are very low compared to spike solution. Furthermore, the detected constituents are not significant contaminants at GAAF or many other AFFF sites. Therefore, the results suggest the mass adsorption over this period of time was insignificant and unlikely to affect groundwater sample results (i.e., create a negative bias).

**Table 26. Summary of Detections Material Compatibility Testing**

| | Positive Bias Testing | | Negative Bias testing | |
|---|---|---|---|---|
| **Compound** | **Geotextile rinsate** | **Geotextile washed with methanol** | **Spike Solution** | **Geotextile after soaking in spike solution** |
| PFOA | 0.97 *I* ng/L | <1.3 µg/kg | 1,000 µg/L | <1.3 µg/kg |
| FOSA | <0.95 ng/L | <1.3 µg/kg | 1,000 µg/L | 4.5 µg/kg |
| PFTeDA | <0.95 ng/L | <1.3 µg/kg | 1,000 µg/L | 47 µg/kg |
| PFTrDA | <0.95 ng/L | <1.3 µg/kg | 1,000 µg/L | 13 µg/kg |

*I* – The reported value is between the laboratory method detection limit and the laboratory practical quantitation limit

### 7.6.2 Data Interpretation

The criteria for this performance objective are considered achieved. No obvious signs of positive or negative bias that would affect data usability have been identified. Based on the data collected in this study, the VWSs can be tested prior to production for certification to be free of primary PFAS-type analytes. It is believed that the well material cleaning process is unnecessary given the negligible amount of PFOA identified in the rinsate sample. However, the methanol rinsing protocol can still

be completed on future VWS installations to ensure VWS materials are PFAS free and will not bias groundwater sample results. In addition, sorption of PFAS to VWS materials was measured indirectly, and the results did not indicate the VWS materials are a significant sink for PFAS. ***Therefore, leaching and adsorption biases are not practical to consider as interference when using VWS and the criteria for this performance objective are considered achieved.***

## 7.7 QUALITATIVE PERFORMANCE OBJECTIVE 1: VWS CAN ASSESS CONTAMINANTS AND CONDITIONS ALONG THE FLOW PATH IN A LONGSECT CONFIGURATION

Both the absolute concentrations of PFAS species and their relative abundance (i.e., concentrations of individual PFAS species relative to each other) may change along the flow path due to PFAS transport and fate properties, geochemical conditions, and release/source mechanisms. A longsect VWS configuration that is oriented along a groundwater flow path orientation may be useful for assessing these conditions and monitoring changes through time. This performance objective is intended to assess the feasibility and usefulness of a longsect VWS configuration.

### 7.7.1 Data Collected

This performance objective was assessed using PFAS concentration data collected from the longsect VWS and compared to data along the flow path collected using vertical data collection methods (i.e., VAP samples and samples from multilevel and conventional wells).

### 7.7.2 Data Interpretation

An eight-screen 477-foot-long VWS was successfully installed in a longsect configuration along an inferred groundwater flow path from the source area near Building 1160 in a south-southeast direction (Figure 11, above). Success will be considered achieved if PFAS concentration data collected from different screen intervals located progressively downgradient follow discernable and consistent trends, indicating the samples represent locations along a flow path. Figure 41, below, shows the average PFOS and PFOA concentrations from the longsect VWS (closed circles series) and nearby VAP and conventional vertical monitoring wells (x series) plotted along the inferred flow path distance. In general, both the PFOS and PFOA data show consistency between the sampling methods and follow a general trend where the first several measurements are similar (approximately 1,100 to 2,400 ng/L for PFOS and 30 to 100 ng/L for PFOA) and then increase by more than 10 times for PFOS (up to 15,500 ng/L) and more than 5 times for PFOA (up to 228 ng/L) approximately 240 feet downgradient. Concentrations then decline somewhat at 275 and 310 feet downgradient.

Figure 42, below, shows the relative concentrations of primary PFAS species (as pie charts) along the inferred flow path distance. Consistently, PFOS, PFOA, and PFHxS are the three most significant PFAS species; however, their relative concentrations gradually change with distance. In a simple system, relative PFAS concentrations would be consistent along the flow path, and concentrations would be expected to be highest near the source (i.e., the first couple of samples along the longsect) with gradually declining concentrations along the flow path. However, imperfect alignment of the longsect with the flow path, temporally variable release history, complex precursor transformation processes, and the comingling contaminants from other sources may be influencing these data.

Currently, it is not possible to definitively conclude the responsible processes; however, the general consistency of VWS data with other sample types and the smoothness of the trend (i.e., high spatial correlation) suggest the well screens were located approximate along a common flow path and that VWS systems can be used to characterize contaminant concentrations in this way, and to assess contaminant transport processes along the flow path.

***As such, the success criteria for this performance objective are considered achieved.*** However, this application of VWSs will be more challenged at sites with significant geologic heterogeneity and variable flow direction.

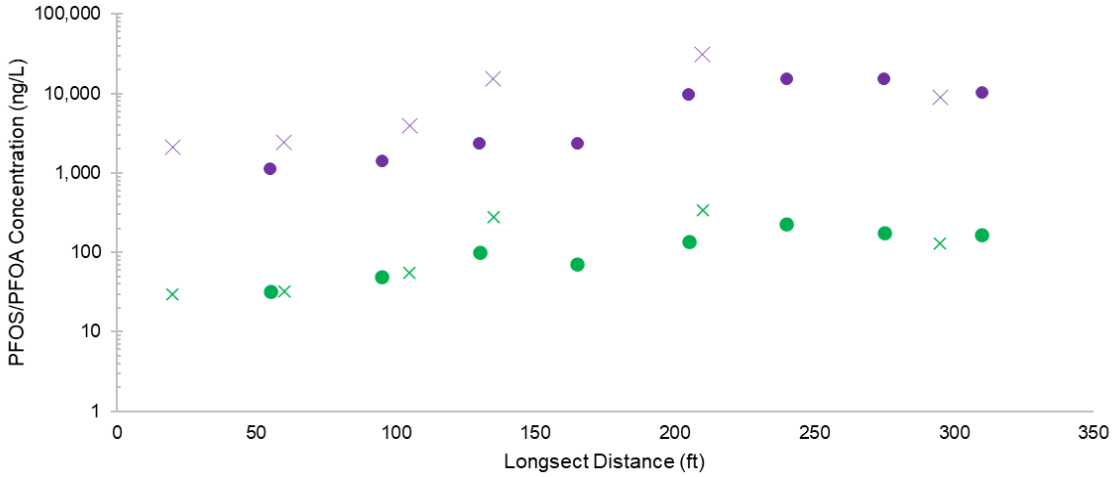

**Figure 41. Average Longsect VWS (circles) and Conventional Monitoring Well (x's) PFOS (purple) and PFOA (green) Concentrations**

One potential future application of a longsect VWS configuration involves evaluation of precursors to terminal PFAS along a flow path over time. Figure 43 presents the sum of target precursors (USEPA Method 1633) and the two most prevalent precursors in this dataset as a fraction of the sum of target PFAS (USEPA Method 1633) along the flow path. In order of frequency of occurrence, potential PFAS precursors detected using Method 1633 include 6:2-FTS, 8:2-fluorotelomer sulfonic acid (8:2-FTS), PFOSA, and 3:3-fluorotelomer carboxylic acid (3:3-FTCA). A decrease in the fraction of total PFAS precursors was observed at downgradient sample locations. A similar decrease was observed in the fractions of 8:2-FTS and to a lesser extent, 6:2-FTS. This observation may reflect biological transformation of precursor mass to terminal perfluoroalkyl carboxylic acids; FTSs are known biological precursors to short chain perfluoroalkyl carboxylic acids (LaFond et al., 2023). Additionally, the dominant precursor species changes from 8:2 FTS in the upgradient portion of the plume to 6:2 FTS downgradient. Differences in sorption characteristics are unlikely to account for the different transport behavior observed in these species based on published experimental organic carbon partitioning constant values and the sand nature of site soils. Also of note are sporadic detections of 3:3-FTCA, a potential degradation product of 4:2-FTS (Harding-Marjanovic et al., 2015), in downgradient locations. Distribution of precursor mass along the flow path may be influenced by production of these species from FTS-precursors and the relative rate of biological degradation of FTSs into FTCAs and ultimately perfluoroalkyl carboxylic acids.

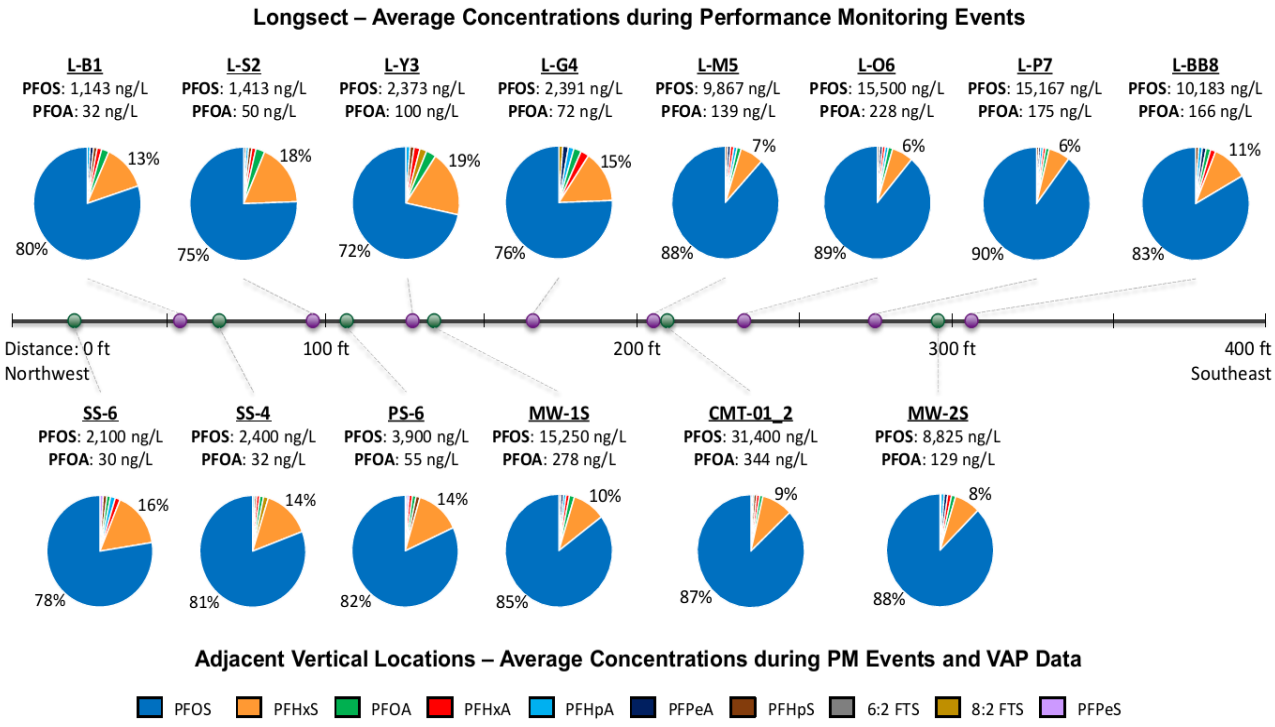

**Figure 42. Relative Concentrations of Primary PFAS Species Along the Inferred Flow Path Distance**

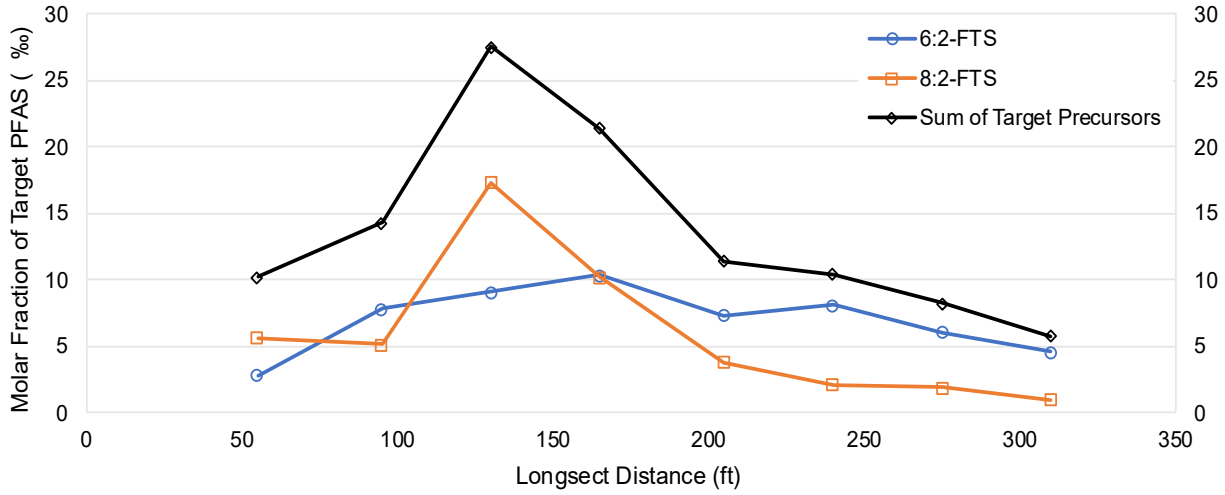

**Figure 43. Distribution of Target PFAS Precursors (6:2-FTS, 8:2-FTS, PFOSA, and 3:3-FTCA) Along the Inferred Flow Path Distance**

## 7.8 QUALITATIVE PERFORMANCE OBJECTIVE 2: DEMONSTRATE INTEGRITY OF GROUT SEALS TO ISOLATE INDIVIDUAL SCREEN SEGMENTS

This performance objective is intended to confirm the integrity of the grout seals separating each well screen segment of the VWS. Seal integrity prevents groundwater from short-circuiting along the well bore and is necessary for sample quality and reliability as well as reliability of hydraulic tests in the screen intervals.

### 7.8.1 Data Collected

Data from two independent methods were used to assess this performance objective:

- A pressure transducer was inserted in VWS screen segments and water was added to adjacent screen segments to detect pressure increases from hydraulic tests in adjacent well screens. No hydraulic response was noted in individual screen segments from pressure changes in adjacent screens.
- The A-DTS system was used to measure temperature under passive and active (heated) conditions from the well bore. Because the different well materials (e.g., grout seals, sediments) exhibit a contrast in thermal conductivity, the position and continuity of seals along the full VWS length were mappable. Thermal response could be quantified two ways: temperature above background during curing and apparent thermal conductivity from A-DTS test.

### 7.8.2 Data Interpretation

This performance criterion is considered successfully achieved based on the following:

- Pressure transducer data do not show clear evidence of seal failure or poor seal construction (e.g., immediate increase in pressure greater than 1 foot of head) during injection testing in adjacent screen intervals.
- The A-DTS data delineate continuous seals that are at least 5 feet long (mean 13 feet, maximum 20 feet) between the five horizontal screens for the shallow VWS.
- The integrity of the grout seals was confirmed for screens installed along the horizontal portion of the VWSs (13 of 18 seals). The grout intervals were difficult to quantify at each end due to screens on a slope and less precise grout injection.

***Overall, grout seals in the horizontal section appear to be placed where intended and are largely functioning as intended (hydraulic separation), as such, this performance objective is considered achieved.***

The shallow and deep VWSs each contained screens on a slope as part of this demonstration where an aggressive ascent angle was implemented to exit, for example, in front of the taxiway. Grout intrusion was observed in those screens based on field water quality parameters (mainly pH) measured during groundwater sampling. This is apparently the result of gravity flow of the grout toward the bottom of the bore. The ends of each bore are able to be grouted from the surface using a flow-down technique (pouring or pumping from the surface) and this was completed during installation.

However, due to this evidence of intrusion, this is only advised after the tremie and proper grouting in bore has been completed and set, and should be done with caution in applicable amounts.

In addition to grout seal issues on the slopes, locating accuracy decreases when drilling at an angle from horizontal as described in Section 7.1. Therefore, during future installations, it is recommended to avoid placing screens on slopes due to potential poor grout seals and decreased locating accuracy. For optimum installation, the bore is recommended to continue horizontally or extend beyond the first and last screens by 10 feet. Additional techniques are possible on a case by cases basis, such as introducing flowing sand on the end of bores and using other EN Rx techniques such as packers for prohibiting grout migration. However, these are not needed if the bore can be properly extended because the seal integrity throughout the horizontal portions of the bore was validated by the data collected.

## 7.9 QUALITATIVE PERFORMANCE OBJECTIVE 3: IDENTIFY CHALLENGES AND LIMITATIONS OF VWSS

This performance objective aims to gather existing practical site implementation and operational considerations to help guide the design of VWSs for monitoring PFAS mass flux/discharge for other sites. This performance criterion is considered successfully achieved because challenges and limitations are understood and can be readily mitigated.

### 7.9.1 Data Collected

Surveys from project personnel involved in installation and system operation, monitoring, sampling, and hydraulic testing were conducted to document implementation challenges or practical considerations throughout the project. Drilling and installation challenges were assessed based on site geologic and hydrogeologic conditions, and experience with the HDD required for the VWS installations.

### 7.9.2 Data Interpretation

This performance criterion is considered successfully achieved because no significant implementation or operational challenges are identified that would limit widespread application of the VWS technology at a broad range of AFFF PFAS sites. Lessons learned from this field demonstration include:

- Avoid installing screens at an angle:
  - Reduced ability to accurately determine placement during drilling
  - Increased risk of grout in screen.
- Limit entry/exit angles to prevent tight bends in the VWS.
- Irresolvable uncertainty in confirming as-built vertical borehole location results in a minimum target thickness of 1 to 1.5 feet.
- Grout delivery methods and options:
  - Concerns for a free-flowing annulus

  - Currently evaluating alternative methods such as a mechanical seal or other means to ensure more precise placement of grout seals.

- Well materials/construction significantly affect hydraulic test results.
- Understanding seasonal water table fluctuations will be important at PFAS sites due to the potential for PFAS to accumulate near the air-water interface. VWS screens installed in high-flux zones near the water table could become dry when groundwater levels decline.
- Although not unique to VWSs, environmental professionals unfamiliar with HDD should be aware that HDD can produce significant amounts of IDW. Considerations should be made for IDW storage and disposal during the planning stage. The following amounts of IDW were generated during this project:
  - *Solid waste*. Waste generated during installation of the VWSs consisted of a mixture of bentonite-based drilling fluid and soil cuttings that was stored in three 20-cubic yard open top roll-off boxes. The high liquid content drilling fluid waste was solidified with an absorbent material to allow disposal as a solid waste stream. The total weight of solidified material was 38 tons with a volume of approximately 45 cubic yards.
  - *Liquid waste*. A total of 2,125 gallons of water was pumped from the VWSs during well development and stored in a 20-cubic-yard vacuum box.

## 7.10 QUALITATIVE PERFORMANCE OBJECTIVE 4: ASSESS ROBUSTNESS OF THE TECHNOLOGY

This performance objective assesses robustness of VWS components to identify if there are design flaws or limitations that should be addressed before the VWS technology is applied at other AFFF PFAS sites.

### 7.10.1 Data Collected

Feedback was obtained from geologists and field staff regarding observed ruggedness and performance of screens, sampling ports, connections, and other well components. Responses included the following:

- The large flush-mount boxes used for this project are rugged and are recommended for future installations.
- Feeding sampling tubes can be challenging; dedicated tubing is recommended to simplify sampling.
- Specialty fittings are required for tracer and slug tests.
- Caps and labels for the individual risers are important for ensuring sample representativeness and proper sample IDs.
- Tight bends may inhibit flow and should be avoided where the well risers enter the well vaults.
- Total VWSs installed to date is more than 200.

- Based on discussion with drillers it may be possible to obtained geologic information after the pilot borehole has been installed using nuclear magnetic resonance imaging geophysical sonde that is pulled through the borehole (e.g., Spurlin et al., 2019). This could be used to confirm geologic interpretations before final VWS design and installation.

### 7.10.2 Data Interpretation

This performance criterion is considered successfully achieved. No fundamental design flaws/ limitations were identified and no systemic problems were experienced during installation and sampling. As of August 2023, more than 200 VWSs have been installed. Lessons learned from previous installations and this ESTCP project will be used to continue improving the design, installation, and sampling processes.

# 8.0 COST ASSESSMENT

This section is intended to provide sufficient cost information such that a remediation professional can reasonably estimate costs for installation of VWSs at a site. In addition, a cost benefit analysis is presented that compares the costs of VWS to a transect of conventional vertical monitoring wells.

## 8.1 COST MODEL

All costs associated with design, installation, and monitoring of VWSs were tracked during the demonstration project. A simple cost model is presented in Table 27, below, and serves as general guidance for estimating the costs of installing VWSs. The costs include:

- Pre-design characterization (see Section 5.2):
  - Five HPT borings
  - Five VAP borings
  - Four vertical fiber optic cables
  - One MLS with seven screens
  - Five conventional monitoring wells.

- VWS materials and installation (see Section 5.4):
  - Three VWSs with total length of 1,390 feet
  - One stand-alone horizontal fiber optic cable
  - Eight screens per VWS for a total of 24 screens
  - Well development
  - Waste disposal
  - Three weeks in the field.

- Performance monitoring and data analysis (see Section 5.6):
  - Twenty-four samples from the VWSs
  - Seven samples from the MLS
  - Five samples from the conventional monitoring wells
  - A-DTS data acquisition.

**Table 27. Cost Model for Three VWSs**

| Cost Element – VWS | Data Tracked During the Demonstration | Unit Cost | Unit | Quantity | Cost |
|---|---|---|---|---|---|
| Pre-design characterization | Labor and equipment costs. | $50,000 | Lump sum | 1 | $50,000 |
| | Drilling subcontractor costs. | $50,000 | Lump sum | 1 | $50,000 |
| | Laboratory costs. | $28,000 | Lump sum | 1 | $28,000 |
| **Subtotal: Pre-Design Characterization** | | | | | **$128,000** |
| Materials: VWS components | Three VWSs with total length of 1,390 feet. | $103,000 | Lump sum | 1 | $103,000 |
| | Risers and grout lines: 0.75-inch HDPE. | | | | |
| | Well screens: 1-inch-diameter HDPE with geotextile screen. Eight screens per system for total of 24 screens. | | | | |
| | A-DTS fiber optic cables. | | | | |
| | Tracer wire: copper clad steel wire. | | | | |
| Installation of VWSs | Utility locating and surveying. | $105,000 | Lump sum | 1 | $105,000 |
| | Drilling equipment mobilization. | | | | |
| | Drilling, reaming, and well installation. | | | | |
| | Well development. | | | | |
| | Grout wells seals. | | | | |
| | Flush-mount vaults. | | | | |
| Waste disposal | Waste characterization: analytical costs. | $3,000 | Lump sum | 1 | $3,000 |
| | Solid and liquid waste disposal: container rental, transportation, and disposal | $30,000 | Lump sum | 1 | $30,000 |
| **Subtotal: VWSs** | | | | | **$241,000** |
| Monitoring | Groundwater sampling and hydraulic testing. | $15,000 | Per event | 8 | $120,000 |
| | A-DTS data acquisition: per monitoring event. | $9,000 | Per event | 8 | $72,000 |
| | Laboratory costs. | $8,000 | Per event | 8 | $64,000 |
| | Flux analysis and 3-D modeling: per monitoring event. | $5,000 | Per event | 8 | $40,000 |
| **Subtotal: Performance Monitoring** | | | | | **$296,000** |

The costs unique to the VWS are the well materials, with most components made of HDPE. For a typical VWS, the well materials will be roughly 50% of the installation costs (excluding waste disposal). The cost of well materials have risen during the last couple of years due to high inflation rates and global supply chain issues. It is difficult to predict how material costs will change in the coming years.

## 8.2 COST DRIVERS

Most remediation professionals are already familiar with the primary factors that influence vertical drilling costs. Most of these same factors also influence costs associated with the HDD method used to install VWSs. There are many variables that impact VWS installation costs and each design is customized based on the objectives of the given project. The main cost drivers of the VWS technology are summarized below:

- *Number of VWSs*. Unit costs for installation of one VWS will be higher due to costs of mobilizing the directional drilling rig and associated equipment. The unit costs decrease when installing multiple VWSs, because the mobilization costs are spread across multiple VWSs.
- *Number of VWS segments and diameter*. A larger number of segments causes the costs to increase in several ways. These include higher cost of well materials (dedicated riser and grout lines to each screen), additional time installing grout seals between the segments, more well development effort, and higher waste disposal costs due to the larger volume of liquid waste produced. The number of segments impact the diameter of the bore; therefore, also increasing drilling costs and drilling waste material costs. Standard VWSs are installed using a 3- or 4-inch-diameter sleeve; therefore, the borehole diameter is fixed. However, if a larger diameter sleeve is used to accommodate more screen intervals/risers, this would increase directional drilling, materials, and waste disposal costs.
- *VWS length and depth*. Well length and depth have a significant impact on the overall installation costs. As length and depth increase, so do the directional drilling and materials costs. Further, the waste disposal costs have a direct relationship to these design parameters due to the larger volume of drilling waste generated during drilling and reaming operations. Usually, the length is a major factor in determining the number of segments and these factors increase together; however, the threshold for larger bores and limitation of length play a part in minimizing cost.
- *Lithology*. Difficult drilling conditions such as dense soils and cobbles result in higher directional drilling costs. Coarser grained formations that are prone to flowing sand conditions and resultant borehole instability will also cause costs to increase. Drilling through bedrock is significantly more costly. These drilling conditions also have consistent cost impact when applying various vertical drilling methodologies that are available for conventional vertical monitoring wells.
- *HDD navigation*. A walkover locating system was used during installation of the VWSs. This locating technology is most often used during HDD. At some project sites, walkover locating may not be applicable due to electromagnetic interference, lack of access above the drill head, or drilling depth greater than approximately 70 feet. Expanded features for walkover tools have reduced the interference, and features like drill-to-box allow some avoidance of common interference; however, at some sites interference can require alternatives.

In these cases, a wireline navigation system would be required. Wireline locating systems include remote magnetic system and gyroscopic steering tools, which are more expensive than the walkover system used for this project. For reference a gyroscopic steering tool would add approximately $6,000 per day while drilling the pilot bore.

## 8.3 COST ANALYSIS

The specific requirements, scale, and geometry of each application will vary. However, product capabilities and limitations can provide a typical application scenario and scalability when examining the cost. To start, drilling speed in typical lithologies is approximately 300 to 400 ft/day. A 300- to 400-foot well system can generally be installed in 2 days (1 day for drilling and 1 day for installation and development). Well systems significantly shorter than 300 feet cannot necessarily be installed in considerably less time, and cost per foot increases appreciably. From this point of 300 feet or greater to the maximum length of typical sleeve sizes (800 to 1,200 feet), the costs are approximately linear. Beyond this distance, rig sizes and sleeve changes increase costs significantly. Also, the well screen spacing and screen length are proportional to the plume width and at these typical spacing distances are practical and only marginal, and linear cost increases are experienced over the total distance. Listed below is a typical and scalable design:

- A site with sandy to silty soils with a water table depth of 10 feet.
- Two transect systems, each 500 feet long with a 10-well screen.
- Risers (¾ inch) for probe and tracer access, with a 4-inch sleeve.
- A 20-foot installation depth, with little to no interference for locating tools.
- Two systems installed with 1,000 feet total of drilling, providing either stacked or multiple transect positions. A total of 20 well screen positions.
- Standard vaults and finishing requirements.
- Traditional drilling, with no rock or other obstructions, and standard drilling mud blends.
- Mobilization of drilling equipment within the region (5 hours or less).
- Includes light mobilization, freight of well system to the central U.S., drilling, and installation.

Based on the model presented in Section 8.1, the estimated drilling and materials cost (for two 500-foot-long VWSs) is approximately $150,000. Note that this analysis does not include oversight, IDW disposal, and sampling costs because these costs vary and depend on site conditions and objectives.

The VWS was designed and invented for its ability to access difficult areas of a site. It is practical to install VWSs with minimal redesign or speeds/installation changes based on surface obstacles (e.g., building, flight line). Minor reorientation of the bore path in the field is common but does not add considerable costs.

# 9.0 IMPLEMENTATION CONSIDERATIONS

VWSs are most advantageous for poorly accessible plumes. The subsurface zones beneath buildings, flight lines, and other obstructions (including natural obstructions, such as ponds or forested areas) can be accessed from alternate surface positions using this technology. However, for optimal design and to maximize the performance of this technology, the following pre-qualifications and considerations are suggested:

- The concentrations and lithology of the plume should be well-understood. The lithology should be understood at the beginning and end of the bore to the final depth. High-resolution site characterization data are recommended for all installations.
- Previous penetrations, well installations, and other vertical environmental equipment should be considered obstacles for the VWS installation. Some previous installations may be suitable for abandonment prior to installation. A buffer distance between the VWS and previous penetrations are recommended at 5 feet or greater. Redevelopment of vertical environmental wells may be required where horizontal drilling encroaches.
- Any anomalies encountered along the length can cause difficult drilling conditions. Research into historical backfilling is recommended for shallower installations.
- Depths shallower than 3 feet may cause difficulty with drilling fluid continuity. Drill fluid surfacing is possible in these shallow settings, especially where other investigative penetrations exist or other utilities allow a pathway to the surface. Often, drilling techniques can regain fluid circulation but time and cost may increase in these settings.
- Depths greater than 60 feet may require additional setbacks and larger drilling equipment. Depths greater than 100 feet likely will require additional specialized tracking equipment.
- Site logistics should be considered. Typically, a minimum of two vehicles (drill rig support truck and vac trailer) are required near the entry position. To access the plume, the entry point can be in any direction from the intended transverse; however, a setback of 3:1 or greater is needed. Also required is space for temporary IDW storage. IDW storage and crew vehicle parking can exist at alternate locations on site.
- An appropriate exit location minimizes installation cost and site time. If an appropriate exit cannot be located, a dead-end bore can be completed for installation. The exit location should have a distance of 3:1 from the depth and end of the last screen position.
- Utilities at the beginning and the end of the bore must be properly marked and at known depths anywhere the depth of the bore is less than 10 to 15 feet. A site walk is recommended prior to design to ensure these utilities can be avoided with direction and depth adjustments.
- Walkover electromagnetic drill bit locating is used along the entire bore length; however, interference often exists inside buildings and other obstacles. Varying the frequencies of the tracking equipment can manage interference. A site walk before design can assess the amount of interference that may be encountered.
- VWSs are custom built and generally require 4 to 8 weeks of processing, construction, and shipping.

- Maintenance of VWSs is similar to that of vertical monitoring wells. VWSs should be protected at the surface with flush mount vaults or protective stickup casings. The risers should be capped to maintain surface integrity. These features should be inspected during each sampling event and repaired if needed. If silting or fouling were to occur, purging and chemical additives can be used to remove scale or biofouling. This has been very rare and only occurred at one site where chemical precipitates resulted from remedial injection reactions. These VWSs were successfully rehabilitated using standard well development methods.
- VWSs are abandoned by grouting in place. Each VWS segment is filled with the proper volume of grout to ensure grout reaches the end of the screen. The risers are then cut off at the surface. It is not practical to abandon the VWS by removal via over drilling. In addition, the tensile strength of the risers is too low to allow extraction of the well materials.

# PROGRAM NARRATIVE

Cascade Technical Services (Cascade) is pleased to present this data report to Arcadis for the Hydraulic Profiling Tool (HPT) services provided between September 9th, 2021 at the Grayling Army Airfield in Grayling, Michigan.

Cascade advanced six HPT borings at the site achieving depths up to approximately 40 feet below ground surface. For each location, Cascade generated a continuous log of the electrical conductivity (EC) and HPT data from ground surface to termination.

Field work, including the operation of the HPT and EC probe, was conducted by trained professionals and quality assurance/quality control (QA/QC) measurements associated with these data were found to be within the tolerances set forth in the standard operating procedures (SOPs) with no exceptions.

Additional information regarding the HPT and EC systems is provided in the reference material included in this report.

I certify that the data package is in compliance with the terms and conditions of the contract and meets Cascade's data quality standards, with no exceptions. Release of the data contained in this package has been authorized by the data manager or his/her designee, as verified by the following signature.

Brad Carlson
Regional Manager, Site Characterization

# QA/QC SUMMARY TABLE

Provided below is a summary of QA/QC information and any deviations from the SOPs that occurred during the field activities.

| Location | Date | Time | Total Depth (ft bgs) | Response Test | Comments / Deviations |
|---|---|---|---|---|---|
| HPT-VRTB-01 | September 9, 2021 | 15:04:27 | 40.2 | Pass | None |
| HPT-VRTB-02 | September 9, 2021 | 16:03:49 | 40.05 | Pass | None |
| HPT-VRTB-03 | September 9, 2021 | 12:40:21 | 40 | Pass | None |
| HPT-VRTB-04 | September 9, 2021 | 17:00:16 | 40.15 | Pass | None |
| HPT-VRTB-05 | September 9, 2021 | 17:46:02 | 40.25 | Pass | None |
| HPT-VRTB-06 | September 9, 2021 | 13:58:28 | 40.2 | Pass | None |

# PROJECT DETAILS

This section provides information regarding the Cascade personnel present at the site during the field activities and the specific equipment used during field activities.

## Cascade Personnel

The following personnel were present during field activities at the Site:

- Rich Regan, HRSC Specialist
- Todd Grossmann Jr., DPT Rig Operator

## Cascade Equipment

The following HRSC equipment was utilized during field activities at the Site:

- Geoprobe 78 Series direct push drill rig
- 1.75-inch O.D. MH6534 HPT probe
- Geoprobe K6300 HPT Controller
- Geoprobe FI 6000 Computer
- 150-foot HPT trunkline
- 1.75-inch O.D. drive rods

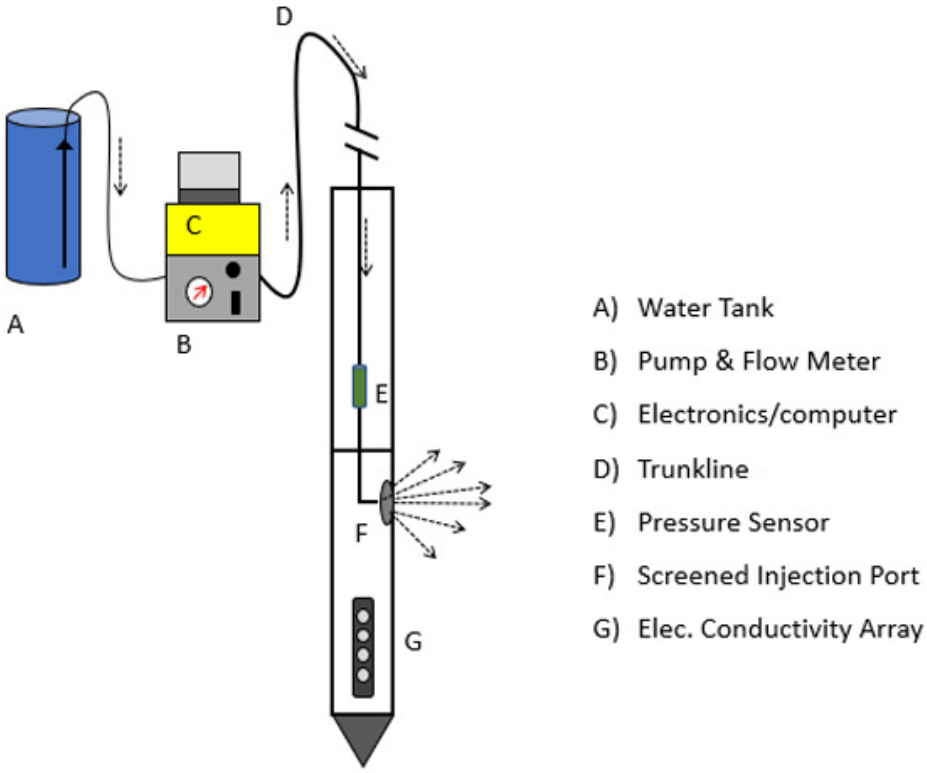
# INTERPRETATION AND RECOMMENDATIONS

This section provides a summary of the data collected during this investigation program, Cascade's recommendations for updating the conceptual site model, and suggestions for next steps in the site management process, including remediation, if appropriate.

## Data Interpretation

A detailed, written interpretation of the data collected during this field event was not included in the contracted scope of work, however, Cascade was in contact with the project team throughout the field mobilization and submitted daily HRSC logs.

## Recommendations



Additional recommendations were not included in this scope of work. Please contact the Cascade Project Manager if you would like to discuss further investigation or remediation alternatives. We would be excited to continue to learn about this site and assist you in meeting your site management goals.

# REFERENCE MATERIAL

This section provides information useful in understanding and interpreting the data logs generated as part of this HRSC investigation.

## HPT System Overview

The hydraulic profiling tool creates a log of the relative formation permeability versus depth in real time as the probe is advanced into the subsurface. It operates by injecting clean water at a constant flow rate from an aboveground reservoir through the direct push rods and out into the surrounding soil via an injection port on the side of the probe. Simultaneously, sensors record the flow rate, the back pressure required by the pump to maintain that flow rate, and the current depth of the probe. These measurements are collected by the onboard software and an estimated hydraulic conductivity (K) value is calculated and plotted alongside the other measurements in real time.

Generalized schematic of the HPT tool. Source: Geoprobe HPT Standard Operating Procedure

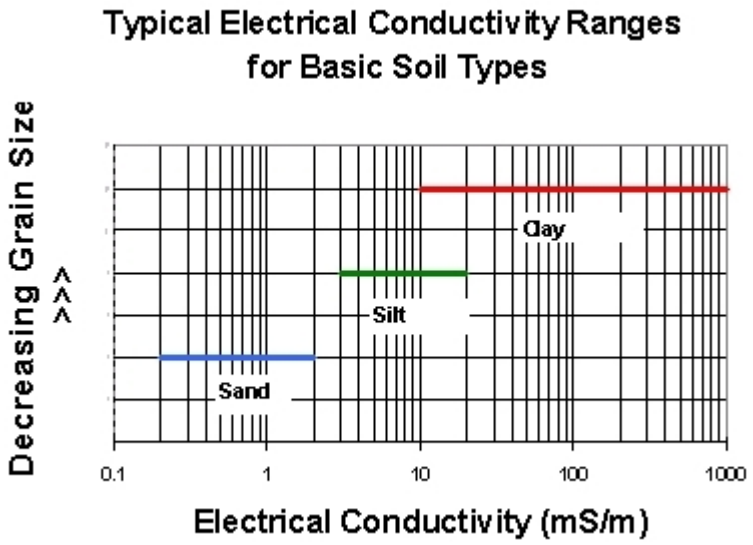
### Reference Testing and Dissipation Tests

Reference testing is conducted to ensure that the HPT pressure transducer is working correctly and to evaluate the condition of the HPT injection screen. The HPT reference test also calculates atmospheric pressure which is required to obtain static water level readings and to determine the estimated K values for the log. The reference test utilizes an apparatus consisting of a tube with a valve located 6 inches above the HPT injection screen and the top of the tube located another 6 inches above the valve. When the tube is filled completely with water, the 12 inches of water will supply an additional 0.433 pounds per square inch (psi) of pressure on the injection screen (in addition to atmospheric pressure). When the valve is opened that additional pressure drops to 0.217 psi at the HPT injection screen. The accuracy of the pressure transducer can be assessed by comparing the pressure readings when the tube is filled and when the tube is filled only to the valve; this is done both with and without the pump running. A tolerance of plus or minus 10 percent is applied for a passing test.

Dissipation tests are conducted to determine the hydrostatic pressure of the water column above the transducer during logging. To conduct a dissipation test, advancement of the tooling is stopped, the HPT pump is stopped, and flow drops to zero. The pressure applied to the HPT pressure transducer by the injection of water into the formation begins to dissipate. This pressure should dissipate to a value equal to atmospheric pressure plus the hydrostatic pressure applied by water in the formation. In post-processing of the HPT log, the dissipation value and the atmospheric pressure determined during reference testing can be used to remove the influence of atmospheric and hydrostatic pressures from the values recorded by the transducer. These adjustments result in the corrected HPT pressure log which is a measure of the properties of the subsurface material.

## HPT Data Interpretation

An HPT log typically includes several types of data, many of which are reduced by the software to generate the estimated K values. The dissipation testing results conducted by the operator during the advancement of the tool are used to adjust the HPT back pressure values to account for the hydrostatic pressure of the water column above the probe during advancement. This adjustment results in the corrected HPT pressure data set. Subsequently, the corrected HPT pressure and the HPT flow data sets are used to calculate the estimated K values.



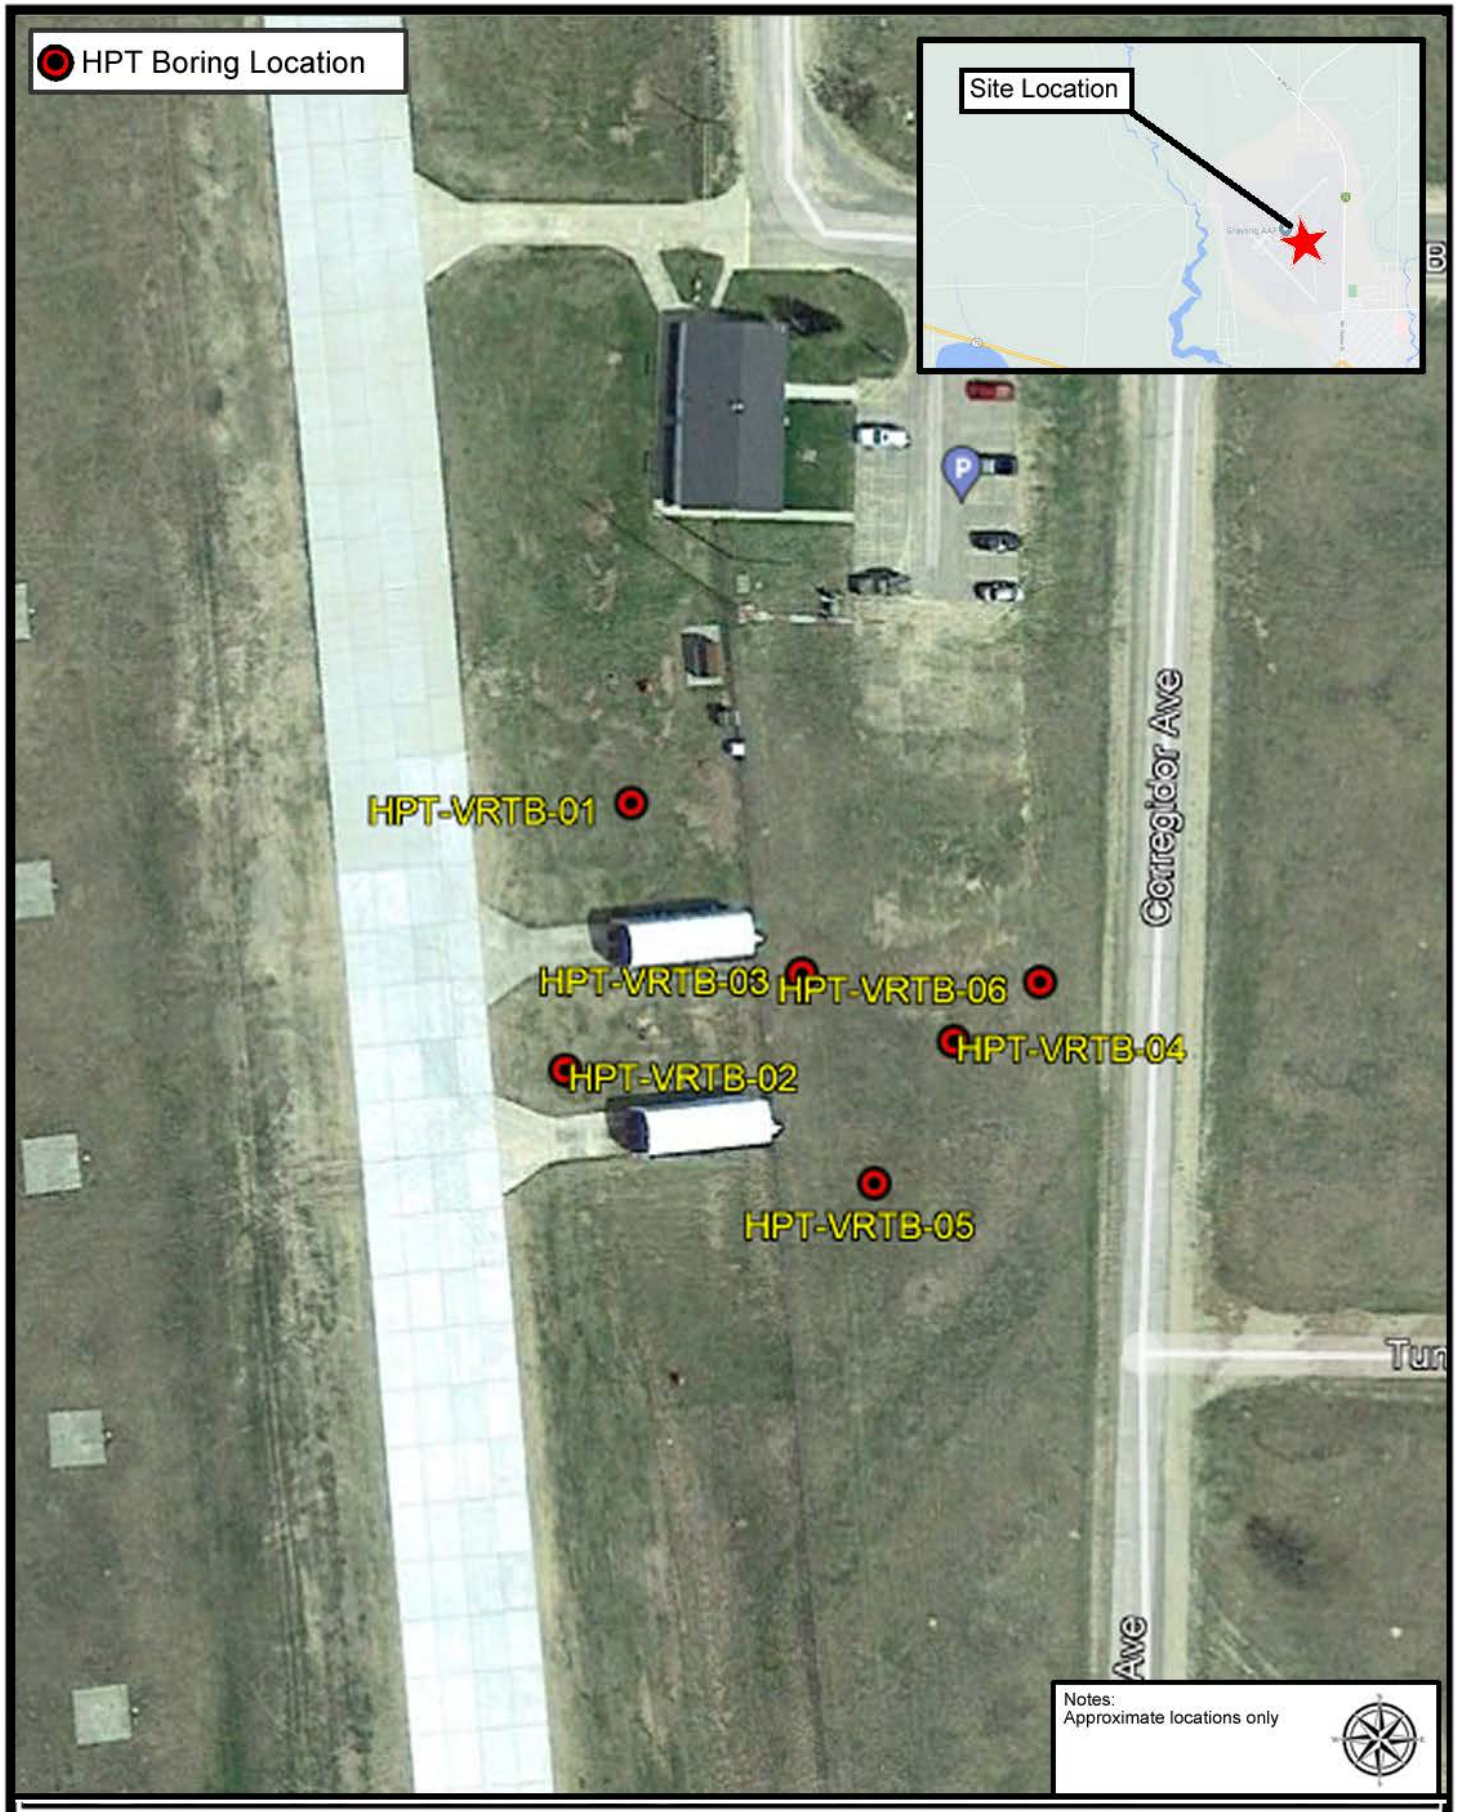
The most useful measurement from the HPT is the estimated K log, which as noted above, is a measure of the relative permeability of the formation versus depth. Despite the fact that these data are presented in units typical of traditional hydraulic conductivity (feet per day), they are not traditional K values and should not be used in many of the applications where a traditional K value would be appropriate. The accuracy of the estimated K values is typically one to two orders of magnitude, which would clearly generate a significant amount of uncertainty if used for any seepage velocity or risk-based calculations. The estimated K values are, however, extremely useful for understanding what zones of the subsurface are exhibiting higher or lower relative permeability.

As a secondary data set from this tool, the HPT back pressure can be helpful in the design of injected remedies. The back pressure is a measure of the level of difficulty faced injecting the

clean water from the HPT system into the formation; this is analogous to level of success an injection may achieve at the same depths.

## EC Data Interpretation

In a general sense, the electrical conductivity of a soil varies with grain size. This correlation can be utilized to gather an understanding of the subsurface from the EC data. The EC measured in the subsurface can also vary based on changes in mineralogy, groundwater geochemistry, and contamination. It is important, then, to confirm the accuracy of the EC data for this use by collecting confirmatory soil borings from your site.



Relationship between electrical conductivity and grain size. Source: Geoprobe Electrical Conductivity System Standard Operating Procedure

## Case Narrative
## Arcadis U.S., Inc.
### Lot Number: WI18005

This Report of Analysis contains the analytical result(s) for the sample(s) listed on the Sample Summary following this Case Narrative. The sample receiving date is documented in the header information associated with each sample.

All results listed in this report relate only to the samples that are contained within this report.

Sample receipt, sample analysis, and data review have been performed in accordance with the Pace Quality Assurance Management Plan (QAMP), applicable Shealy standard operating procedures (SOPs), the 2003 NELAC standard, and Shealy policies. Additionally, the DoD QSM version 5.3 has been followed for these samples, and specifically Table B-15 was followed for all PFAS samples. Any exceptions to the QAMP, SOPs, NELAC standards, the DoD QSM, or policies are qualified on the results page or discussed below.

All QC associated with these samples was in compliance with DOD QSM 5.3 table B-15 and our PFAS SOP.

Correction factors (CF) are used to calculate the original sample concentration. The CF is the inverse of the concentration factor (sample volume / extract final volume) times the dilution factor (DF). For undiluted analysis. For undiluted analysis, the extract is prepared for injection by adding 182 uL of sample extract + 8 uL of reagent water + 10 uL of internal standard solution to a polypropylene autosampler vial. An extra correction factor of 0.91 (182 uL / 200 uL = 0.91) applies. The CF is calculated as follows:

CF = DF * FV / Vo

FV is volume of extract (mL)
Vo is initial sample volume (mL)
DF is dilution factor. For undiluted analysis, DF = 1/0.91.

Sample concentration for aqueous samples:
Concentration (ng/L) = Cs*CF,

$$C_s = \frac{\left(\frac{(A_s x C_{is})}{A_{is}}\right) - B}{M1}$$

Where

$C_s$ is on column concentration of target analyte in the sample (ng/L)
$C_{is}$ is concentration of internal standard in the sample (ng/L)
$A_s$ is peak response of target analyte in the sample
$A_{is}$ is peak response of internal standard in the sample
M1 is the average RF from ICAL or the slope from linear regression ICAL
B is the y-intercept from the ICAL

Biological Tissue: All, Non-Potable Water: SGT-HEM EPA 1664B, Silica EPA 200.7, Boron, Calcium, Silicon, Strontium EPA 200.8, Bicarbonate, Carbonate, and Hydroxide Alkalinity SM 2320 B-2011, Fecal Coliform SM 9221 C E-2006 & SM 9222D-2006, Strontium SW-846 6010D, VOC SM 6200 B-2011, Drinking Water: VOC (excluding BTEX, MTBE, Naphthalene, & 1,2-dichloroethane) EPA 524.2, Solid Chemical Material: TOC Walkley-Black.

If you have any questions regarding this report please contact the Pace Project Manager listed on the cover page.

Samples WI18005-001, WI18005-002 required centrifugation prior to extraction, due to excessive solids present in the samples. Centrifugation was performed following the PFAS Aqueous Centrifuge Protocol; samples were spiked with Surrogate (SUR; Extracted Internal Standard/EIS) and shaken vigorously before being poured into a conical bottle and centrifuged. The centrifuged aqueous sample was decanted back into the original sample bottle, off of the condensed solids remaining in the centrifuge bottle. Original sample bottle was rinsed as normal and centrifuge bottle was rinsed with 4mL of MeOH. Centrifuge bottle rinsate was added to the elution. Samples concentrated to <10mL and reconstituted to 10mL using MeOH by transfer pipet.

Surrogate recovery for the following samples were outside control limits: WI18005-008, WI18005-009. Evidence of matrix interference is present; therefore, re-extraction and/or re-analysis was not performed.

Surrogate recovery for the following samples was outside the upper control limit: WI18005-001, WI18005-002, WI18005-005, WI18005-010. This sample did not contain any target analytes; therefore, re-extraction and/or re-analysis was not performed.

The MS/MSD associated with sample WI18005-004 had multiple analytes recovered outside of the acceptance limits. The LCS was recovered within the required acceptance limits; therefore, this demonstrates a matrix effect and data quality is not impacted.

The laboratory control sample (LCS) and / or laboratory control sample duplicate (LCSD) for prep batch 18205 exceeded acceptance criteria for the 6:2-FTS EIS compound. 6-FTS was not detected in the samples affected: WI18005-001, WI18005-002.

The method blank for prep batch 18279 contained analyte 6:2 FTS was greater than the acceptance criteria. The associated samples, WI18005-004, WI18005-005, WI18005-008, WI18005-009 did not contain detections and/or less than 1/2 of LOQ for the target analyte; therefore, re-extraction and/or re-analysis of samples was not performed. The data has been reported.

The method blank for prep batch 18955 contained analyte: 6:2 FTS greater than the acceptance criteria. The associated sample, WI18005-006, WI18005-007 was re-prepped and re-analyzed outside of holding time. Both sets of data has been reported.

LOQ = Limit of Quantitation
U = Not detected at or above the LOQ
H = Out of holding time
B = Detected in the method blank
N = Recovery is out of criteria
W = Reported on wet weight basis
E = Quantitation of compound exceeded the calibration range
P = The RPD between two GC columns exceeds 40%
LOD = Limit of Detection
DL = Detection Limit
J = Estimated result < LOQ and ≥ DL
Q = Surrogate failure
L = LCS/LCSD failure
S = MS/MSD failure

LOQ = Limit of Quantitation
U = Not detected at or above the LOQ
H = Out of holding time
B = Detected in the method blank
N = Recovery is out of criteria
W = Reported on wet weight basis
E = Quantitation of compound exceeded the calibration range
P = The RPD between two GC columns exceeds 40%
LOD = Limit of Detection
DL = Detection Limit
J = Estimated result < LOQ and ≥ DL
Q = Surrogate failure
L = LCS/LCSD failure
S = MS/MSD failure

LOQ = Limit of Quantitation
U = Not detected at or above the LOQ
H = Out of holding time
B = Detected in the method blank
N = Recovery is out of criteria
W = Reported on wet weight basis
E = Quantitation of compound exceeded the calibration range
P = The RPD between two GC columns exceeds 40%
LOD = Limit of Detection
DL = Detection Limit
J = Estimated result < LOQ and ≥ DL
Q = Surrogate failure
L = LCS/LCSD failure
S = MS/MSD failure

Samples Receipt Checklist (SRC) (ME0018C-15)
Issuing Authority: Pace ENV - WCOL

Revised: 9/29/2020

# Sample Receipt Checklist (SRC)

Client: ARCADIS  Cooler Inspected by/date: JRG2 / 09/18/2021  Lot #: WI18035

Means of receipt: ☐ Pace ☐ Client ☐ UPS ☑ FedEx ☐ Other:

| | | | |
|---|---|---|---|
| ☑ Yes | ☐ No | | 1. Were custody seals present on the cooler? |
| ☑ Yes | ☐ No | ☐ NA | 2. If custody seals were present, were they intact and unbroken? |

pH Strip ID: NA  Chlorine Strip ID: NA  Tested by: NA

Original temperature upon receipt / Derived (Corrected) temperature upon receipt  %Solid Snap-Cup ID: NA

3.5 / 3.5 °C  NA / NA °C  NA / NA °C  NA / NA °C

Method: ☑ Temperature Blank ☐ Against Bottles  IR Gun ID: 5  IR Gun Correction Factor: 0 °C

Method of coolant: ☑ Wet Ice ☐ Ice Packs ☐ Dry Ice ☐ None

| | | | |
|---|---|---|---|
| ☐ Yes | ☐ No | ☑ NA | 3. If temperature of any cooler exceeded 6.0°C, was Project Manager Notified? PM was Notified by: phone / email / face-to-face (circle one). |
| ☑ Yes | ☐ No | ☐ NA | 4. Is the commercial courier's packing slip attached to this form? |
| ☑ Yes | ☐ No | | 5. Were proper custody procedures (relinquished/received) followed? |
| ☑ Yes | ☐ No | | 6. Were sample IDs listed on the COC? |
| ☑ Yes | ☐ No | | 7. Were sample IDs listed on all sample containers? |
| ☑ Yes | ☐ No | | 8. Was collection date & time listed on the COC? |
| ☑ Yes | ☐ No | | 9. Was collection date & time listed on all sample containers? |
| ☑ Yes | ☐ No | | 10. Did all container label information (ID, date, time) agree with the COC? |
| ☑ Yes | ☐ No | | 11. Were tests to be performed listed on the COC? |
| ☑ Yes | ☐ No | | 12. Did all samples arrive in the proper containers for each test and/or in good condition (unbroken, lids on, etc.)? |
| ☑ Yes | ☐ No | | 13. Was adequate sample volume available? |
| ☐ Yes | ☑ No | | 14. Were all samples received within ½ the holding time or 48 hours, whichever comes first? |
| ☐ Yes | ☑ No | | 15. Were any samples containers missing/excess (circle one) samples Not listed on COC? |
| ☐ Yes | ☐ No | ☑ NA | 16. For VOA and RSK-175 samples, were bubbles present >"pea-size" (¼" or 6mm in diameter) in any of the VOA vials? |
| ☐ Yes | ☐ No | ☑ NA | 17. Were all DRO/metals/nutrient samples received at a pH of < 2? |
| ☐ Yes | ☐ No | ☑ NA | 18. Were all cyanide samples received at a pH > 12 and sulfide samples received at a pH > 9? |
| ☐ Yes | ☐ No | ☑ NA | 19. Were all applicable $NH_3$/TKN/cyanide/phenol/625.1/608.3 (< 0.5mg/L) samples free of residual chlorine? |
| ☐ Yes | ☐ No | ☑ NA | 20. Were client remarks/requests (i.e. requested dilutions, MS/MSD designations, etc...) correctly transcribed from the COC into the comment section in LIMS? |
| ☐ Yes | ☑ No | | 21. Was the quote number listed on the container label? If yes, Quote # NA |

**Sample Preservation** (Must be completed for any sample(s) incorrectly preserved or with headspace.)

Sample(s) NA were received incorrectly preserved and were adjusted accordingly in sample receiving with NA mL of circle one: H2SO4, HNO3, HCl, NaOH using SR # NA.
Time of preservation NA. If more than one preservative is needed, please note in the comments below.

Sample(s) NA were received with bubbles >6 mm in diameter.

Samples(s) NA were received with TRC > 0.5 mg/L (If #19 is ***no***) and were adjusted accordingly in sample receiving with sodium thiosulfate ($Na_2S_2O_3$) with Shealy ID: NA.

## Case Narrative
## Arcadis U.S., Inc.
### Lot Number: WI18006

This Report of Analysis contains the analytical result(s) for the sample(s) listed on the Sample Summary following this Case Narrative. The sample receiving date is documented in the header information associated with each sample.

All results listed in this report relate only to the samples that are contained within this report.

Sample receipt, sample analysis, and data review have been performed in accordance with the most current approved The NELAC Institute (TNI) standards, the Pace Analytical Services, LLC ("Pace") Laboratory Quality Manual, standard operating procedures (SOPs), and Pace policies. Additionally, the DoD QSM version 5.3 has been followed for these samples, and specifically Table B-15 was followed for all PFAS samples. Any exceptions to the TNI standards, the Laboratory Quality Manual, SOPs, the DoD QSM, or policies are qualified on the results page or discussed below.

Pace is a TNI accredited laboratory; however, the following analyses are currently not listed on our TNI scope of accreditation:

Biological Tissue: All, Non-Potable Water: SGT-HEM EPA 1664B, Silica EPA 200.7, Boron, Calcium, Silicon, Strontium EPA 200.8, Bicarbonate, Carbonate, and Hydroxide Alkalinity SM 2320 B-2011, Fecal Coliform SM 9221 C E-2006 & SM 9222D-2006, Strontium SW-846 6010D, VOC SM 6200 B-2011, Drinking Water: VOC (excluding BTEX, MTBE, Naphthalene, & 1,2-dichloroethane) EPA 524.2, Solid Chemical Material: TOC Walkley-Black.

If you have any questions regarding this report please contact the Pace Project Manager listed on the cover page.

Samples WI18006-001, WI18006-003, WI18006-006 required centrifugation prior to extraction, due to excessive solids present in the samples. Centrifugation was performed following the PFAS Aqueous Centrifuge Protocol; samples were spiked with Surrogate (SUR; Extracted Internal Standard/EIS) and shaken vigorously before being poured into 6 50mL tubes and centrifuged. The centrifuged aqueous sample was decanted back into the original sample bottle, off of the condensed solids remaining in the centrifuge tubes. Original sample bottle was rinsed as normal and centrifuge tubes were rinsed with 0.5mL of MeOH each (total of 3mL). Centrifuge bottle rinsate was added to the elution. Samples concentrated to <10mL and reconstituted to 10mL using MeOH by transfer pipet.

Surrogate recovery for the following sample was outside the upper control limit: WI18006-002. This sample did not contain any target analytes; therefore, re-extraction and/or re-analysis was not performed.

Surrogate recovery for the following sample was outside control limits: WI18006-003. Evidence of matrix interference is present; therefore, re-extraction and/or re-analysis was not performed.

LOQ = Limit of Quantitation
U = Not detected at or above the LOQ
H = Out of holding time
B = Detected in the method blank
N = Recovery is out of criteria
W = Reported on wet weight basis
E = Quantitation of compound exceeded the calibration range
P = The RPD between two GC columns exceeds 40%
LOD = Limit of Detection
DL = Detection Limit
J = Estimated result < LOQ and ≥ DL
Q = Surrogate failure
L = LCS/LCSD failure
S = MS/MSD failure

LOQ = Limit of Quantitation
B = Detected in the method blank
E = Quantitation of compound exceeded the calibration range
DL = Detection Limit
Q = Surrogate failure
U = Not detected at or above the LOQ
N = Recovery is out of criteria
P = The RPD between two GC columns exceeds 40%
J = Estimated result < LOQ and ≥ DL
L = LCS/LCSD failure
H = Out of holding time
W = Reported on wet weight basis
LOD = Limit of Detection
S = MS/MSD failure

| ☑ Yes | ☐ No | | 8. Was collection date & time listed on the COC? |
| ☑ Yes | ☐ No | | 9. Was collection date & time listed on all sample containers? |
| ☑ Yes | ☐ No | | 10. Did all container label information (ID, date, time) agree with the COC? |
| ☑ Yes | ☐ No | | 11. Were tests to be performed listed on the COC? |
| ☑ Yes | ☐ No | | 12. Did all samples arrive in the proper containers for each test and/or in good condition (unbroken, lids on, etc.)? |
| ☑ Yes | ☐ No | | 13. Was adequate sample volume available? |
| ☐ Yes | ☑ No | | 14. Were all samples received within ½ the holding time or 48 hours, whichever comes first? |
| ☐ Yes | ☑ No | | 15. Were any samples containers missing/excess (circle one) samples Not listed on COC? |
| ☐ Yes | ☐ No | ☑ NA | 16. For VOA and RSK-175 samples, were bubbles present >"pea-size" (¼"or 6mm in diameter) in any of the VOA vials? |
| ☐ Yes | ☐ No | ☑ NA | 17. Were all DRO/metals/nutrient samples received at a pH of < 2? |
| ☐ Yes | ☐ No | ☑ NA | 18. Were all cyanide samples received at a pH > 12 and sulfide samples received at a pH > 9? |
| ☐ Yes | ☐ No | ☑ NA | 19. Were all applicable $NH_3$/TKN/cyanide/phenol/625.1/608.3 (< 0.5mg/L) samples free of residual chlorine? |
| ☐ Yes | ☐ No | ☑ NA | 20. Were client remarks/requests (i.e. requested dilutions, MS/MSD designations, etc...) correctly transcribed from the COC into the comment section in LIMS? |
| ☐ Yes | ☑ No | | 21. Was the quote number listed on the container label? If yes, Quote # NA |

**Sample Preservation** (Must be completed for any sample(s) incorrectly preserved or with headspace.)

Sample(s) NA were received incorrectly preserved and were adjusted accordingly in sample receiving with NA mL of circle one: $H_2SO_4$, $HNO_3$, HCl, NaOH using SR # NA.

Time of preservation NA. If more than one preservative is needed, please note in the comments below.

Sample(s) NA were received with bubbles >6 mm in diameter.

Samples(s) NA were received with TRC > 0.5 mg/L (If #19 is *no*) and were adjusted accordingly in sample receiving with sodium thiosulfate ($Na_2S_2O_3$) with Shealy ID: NA.

RE: Project: WI18006 Arcadis
Pace Project No.: 10580325

Dear Kathy Smith:

Enclosed are the analytical results for sample(s) received by the laboratory on September 24, 2021. The results relate only to the samples included in this report. Results reported herein conform to the applicable TNI/NELAC Standards and the laboratory's Quality Manual, where applicable, unless otherwise noted in the body of the report.

The test results provided in this final report were generated by each of the following laboratories within the Pace Network:

- Pace Analytical Services - Minneapolis

If you have any questions concerning this report, please feel free to contact me.

Sincerely,

Ashley Williams

# PROJECT NARRATIVE

Project: WI18006 Arcadis
Pace Project No.: 10580325

**Method:** **True TOF**
**Description:** Total Organofluorine
**Client:** Pace West Columbia,SC
**Date:** November 02, 2021

**General Information:**
6 samples were analyzed for True TOF by Pace Analytical Services Minneapolis. All samples were received in acceptable condition with any exceptions noted below or on the chain-of custody and/or the sample condition upon receipt form (SCUR) attached at the end of this report.

**Hold Time:**
The samples were analyzed within the method required hold times with any exceptions noted below.

H1: Analysis conducted outside the recognized method holding time.
- VAP-VRTB-03_36-40 (Lab ID: 10580325001)

H5: Reanalysis conducted in excess of EPA method holding time. Results confirm original analysis performed in hold time.
- VAP-VRTB-03_15-19 (Lab ID: 10580325006)
- VAP-VRTB-03_19-23 (Lab ID: 10580325005)
- VAP-VRTB-03_23-27 (Lab ID: 10580325004)
- VAP-VRTB-03_27.5-31.5 (Lab ID: 10580325003)
- VAP-VRTB-03_32-36 (Lab ID: 10580325002)

**Method Blank:**
All analytes were below the report limit in the method blank, where applicable, with any exceptions noted below.

**Laboratory Control Spike:**
All laboratory control spike compounds were within QC limits with any exceptions noted below.

**Matrix Spikes:**
All percent recoveries and relative percent differences (RPDs) were within acceptance criteria with any exceptions noted below.

QC Batch: 778366

A matrix spike and/or matrix spike duplicate (MS/MSD) were performed on the following sample(s): 10583596001

M3: Matrix spike recovery was outside laboratory control limits due to matrix interferences.
- MSD (Lab ID: 4145516)
  - Total Organofluorine

R2: RPD value was outside control limits due to matrix interference
- MSD (Lab ID: 4145516)
  - Total Organofluorine

**Additional Comments:**

Analyte Comments:

QC Batch: 778366

N2: The lab does not hold NELAC/TNI accreditation for this parameter but other accreditations/certifications may apply. A complete list of accreditations/certifications is available upon request.
- BLANK (Lab ID: 4145513)
  - Free Fluoride

# QUALIFIERS

Project: WI18006 Arcadis
Pace Project No.: 10580325

## DEFINITIONS

DF - Dilution Factor, if reported, represents the factor applied to the reported data due to dilution of the sample aliquot.

ND - Not Detected at or above adjusted reporting limit.

TNTC - Too Numerous To Count

J - Estimated concentration above the adjusted method detection limit and below the adjusted reporting limit.

MDL - Adjusted Method Detection Limit.

PQL - Practical Quantitation Limit.

RL - Reporting Limit - The lowest concentration value that meets project requirements for quantitative data with known precision and bias for a specific analyte in a specific matrix.

S - Surrogate

1,2-Diphenylhydrazine decomposes to and cannot be separated from Azobenzene using Method 8270. The result for each analyte is a combined concentration.

Consistent with EPA guidelines, unrounded data are displayed and have been used to calculate % recovery and RPD values.

LCS(D) - Laboratory Control Sample (Duplicate)

MS(D) - Matrix Spike (Duplicate)

DUP - Sample Duplicate

RPD - Relative Percent Difference

NC - Not Calculable.

SG - Silica Gel - Clean-Up

U - Indicates the compound was analyzed for, but not detected.

N-Nitrosodiphenylamine decomposes and cannot be separated from Diphenylamine using Method 8270. The result reported for each analyte is a combined concentration.

Reported results are not rounded until the final step prior to reporting. Therefore, calculated parameters that are typically reported as "Total" may vary slightly from the sum of the reported component parameters.

Pace Analytical is TNI accredited. Contact your Pace PM for the current list of accredited analytes.

TNI - The NELAC Institute.

## ANALYTE QUALIFIERS

| | |
|---|---|
| H1 | Analysis conducted outside the recognized method holding time. |
| H5 | Reanalysis conducted in excess of EPA method holding time. Results confirm original analysis performed in hold time. |
| M3 | Matrix spike recovery was outside laboratory control limits due to matrix interferences. |
| N2 | The lab does not hold NELAC/TNI accreditation for this parameter but other accreditations/certifications may apply. A complete list of accreditations/certifications is available upon request. |
| R2 | RPD value was outside control limits due to matrix interference |

## Case Narrative
## Arcadis U.S., Inc.
### Lot Number: WI18007

This Report of Analysis contains the analytical result(s) for the sample(s) listed on the Sample Summary following this Case Narrative. The sample receiving date is documented in the header information associated with each sample.

All results listed in this report relate only to the samples that are contained within this report.

Sample receipt, sample analysis, and data review have been performed in accordance with the Pace Quality Assurance Management Plan (QAMP), applicable Shealy standard operating procedures (SOPs), the 2003 NELAC standard, and Shealy policies. Additionally, the DoD QSM version 5.3 has been followed for these samples, and specifically Table B-15 was followed for all PFAS samples. Any exceptions to the QAMP, SOPs, NELAC standards, the DoD QSM, or policies are qualified on the results page or discussed below.

All QC associated with these samples was in compliance with DOD QSM 5.3 table B-15 and our PFAS SOP.

Correction factors (CF) are used to calculate the original sample concentration. The CF is the inverse of the concentration factor (sample volume / extract final volume) times the dilution factor (DF). For undiluted analysis. For undiluted analysis, the extract is prepared for injection by adding 182 uL of sample extract + 8 uL of reagent water + 10 uL of internal standard solution to a polypropylene autosampler vial. An extra correction factor of 0.91 (182 uL / 200 uL = 0.91) applies. The CF is calculated as follows:

CF = DF * FV / Vo

FV is volume of extract (mL)
Vo is initial sample volume (mL)
DF is dilution factor. For undiluted analysis, DF = 1/0.91.

Sample concentration for aqueous samples:
Concentration (ng/L) = Cs*CF,

$$C_s = \frac{\left(\frac{(A_s x C_{is})}{A_{is}}\right) - B}{M1}$$

Where

$C_s$ is on column concentration of target analyte in the sample (ng/L)
$C_{is}$ is concentration of internal standard in the sample (ng/L)
$A_s$ is peak response of target analyte in the sample
$A_{is}$ is peak response of internal standard in the sample
M1 is the average RF from ICAL or the slope from linear regression ICAL
B is the y-intercept from the ICAL

Pace is a TNI accredited laboratory; however, the following analyses are currently not listed on our TNI scope of accreditation:

Biological Tissue: All, Non-Potable Water: SGT-HEM EPA 1664B, Silica EPA 200.7, Boron, Calcium, Silicon, Strontium EPA 200.8, Bicarbonate, Carbonate, and Hydroxide Alkalinity SM 2320 B-2011, Fecal Coliform SM 9221 C E-2006 & SM 9222D-2006, Strontium SW-846 6010D, VOC SM 6200 B-2011, Drinking Water: VOC (excluding BTEX, MTBE, Naphthalene, & 1,2-dichloroethane) EPA 524.2, Solid Chemical Material: TOC Walkley-Black.

Where applicable, all soil sample results (including LOQ and DL if requested) are corrected for dry weight unless flagged with a "W" qualifier.

If you have any questions regarding this report please contact the Pace Project Manager listed on the cover page.

For samples WI18007-001 and WI18007-012, sample matrix prevented full volume from being extracted, precluding method mandated bottle rinse. Elution solvent was aliquoted directly into the reservoir, rinsing the inside. Surrogate recovery may be adversely affected.

Samples WI18007-001, WI18007-002, WI18007-003, WI18007-009, WI18007-010, WI18007-011, and WI18007-013 required centrifugation prior to extraction, due to excessive solids present in the samples. Centrifugation was performed following the PFAS Aqueous Centrifuge Protocol; samples were spiked with Surrogate (SUR; Extracted Internal Standard/EIS) and shaken vigorously before being poured into 6 50mL tubes and centrifuged. The centrifuged aqueous sample was decanted back into the original sample bottle, off of the condensed solids remaining in the centrifuge tubes. Original sample bottle was rinsed as normal and centrifuge tubes were rinsed with 0.5mL of MeOH each (total of 3mL). Centrifuge bottle rinsate was added to the elution. Samples concentrated to <10mL and reconstituted to 10mL using MeOH by transfer pipet.

The continuing calibration verification (CCV) associated with sample(s) WI18006-001, WI18006-002, WI18006-003, WI18007-014, WI18007-015, WI18007-016 recovered above the upper control limit for the 4:2-FTS EIS compound. The sample(s) associated with this CCV were non-detect for the affected analyte; therefore, the data has been reported.

The laboratory control sample (LCS) and / or laboratory control sample duplicate (LCSD) for prep batch 18205 exceeded acceptance criteria for the 6:2-FTS EIS compound. 6-FTS was not detected in the follwing samples: WI18007-003, WI18007-004, WI18007-006. Other samples were re-extracted and re-analyzed outside of holding time, both sets of data have been reported.

Surrogate recovery for the following sample was outside the upper control limit: WI18007-003, WI18007-006, WI18007-014, WI18007-016. This sample did not contain any target analytes; therefore, re-extraction and/or re-analysis was not performed.

Surrogate recovery for the following sample(s) was outside control limits: WI18007-013. Evidence of matrix interference is present; therefore, re-extraction and/or re-analysis was not performed.

The MS/MSD associated with sample WI18006-007 had multiple analytes recovered outside of the acceptance limits. The LCS was recovered within the required acceptance limits; therefore, this demonstrates a matrix effect and data quality is not impacted.

## Sample Summary

LOQ = Limit of Quantitation
U = Not detected at or above the LOQ
H = Out of holding time
B = Detected in the method blank
N = Recovery is out of criteria
W = Reported on wet weight basis
E = Quantitation of compound exceeded the calibration range
P = The RPD between two GC columns exceeds 40%
LOD = Limit of Detection
DL = Detection Limit
J = Estimated result < LOQ and ≥ DL
Q = Surrogate failure
L = LCS/LCSD failure
S = MS/MSD failure

LOQ = Limit of Quantitation
U = Not detected at or above the LOQ
H = Out of holding time
B = Detected in the method blank
N = Recovery is out of criteria
W = Reported on wet weight basis
E = Quantitation of compound exceeded the calibration range
P = The RPD between two GC columns exceeds 40%
LOD = Limit of Detection
DL = Detection Limit
J = Estimated result < LOQ and ≥ DL
Q = Surrogate failure
L = LCS/LCSD failure
S = MS/MSD failure

LOQ = Limit of Quantitation
U = Not detected at or above the LOQ
H = Out of holding time
B = Detected in the method blank
N = Recovery is out of criteria
W = Reported on wet weight basis
E = Quantitation of compound exceeded the calibration range
P = The RPD between two GC columns exceeds 40%
LOD = Limit of Detection
DL = Detection Limit
J = Estimated result < LOQ and ≥ DL
Q = Surrogate failure
L = LCS/LCSD failure
S = MS/MSD failure

LOQ = Limit of Quantitation
U = Not detected at or above the LOQ
H = Out of holding time
B = Detected in the method blank
N = Recovery is out of criteria
W = Reported on wet weight basis
E = Quantitation of compound exceeded the calibration range
P = The RPD between two GC columns exceeds 40%
LOD = Limit of Detection
DL = Detection Limit
J = Estimated result < LOQ and ≥ DL
Q = Surrogate failure
L = LCS/LCSD failure
S = MS/MSD failure

LOQ = Limit of Quantitation
U = Not detected at or above the LOQ
H = Out of holding time
B = Detected in the method blank
N = Recovery is out of criteria
W = Reported on wet weight basis
E = Quantitation of compound exceeded the calibration range
P = The RPD between two GC columns exceeds 40%
LOD = Limit of Detection
DL = Detection Limit
J = Estimated result < LOQ and ≥ DL
Q = Surrogate failure
L = LCS/LCSD failure
S = MS/MSD failure

LOQ = Limit of Quantitation
U = Not detected at or above the LOQ
H = Out of holding time
B = Detected in the method blank
N = Recovery is out of criteria
W = Reported on wet weight basis
E = Quantitation of compound exceeded the calibration range
P = The RPD between two GC columns exceeds 40%
LOD = Limit of Detection
DL = Detection Limit
J = Estimated result < LOQ and ≥ DL
Q = Surrogate failure
L = LCS/LCSD failure
S = MS/MSD failure

U = Not detected at or above the LOQ
H = Out of holding time
B = Detected in the method blank
N = Recovery is out of criteria
W = Reported on wet weight basis
E = Quantitation of compound exceeded the calibration range
P = The RPD between two GC columns exceeds 40%
LOD = Limit of Detection
DL = Detection Limit
J = Estimated result < LOQ and ≥ DL
Q = Surrogate failure
L = LCS/LCSD failure
S = MS/MSD failure

Samples Receipt Checklist (SRC) (ME0018C-15)
Issuing Authority: Pace ENV - WCOL

Revised: 9/29/2020

# Sample Receipt Checklist (SRC)

Client: ARCADIS  Cooler Inspected by/date: JRG2 / 09/18/2021  Lot #: W118697

Means of receipt: ☐ Pace ☐ Client ☐ UPS ☑ FedEx ☐ Other: _____

| | | | |
|---|---|---|---|
| ☐ Yes | ☑ No | | 1. Were custody seals present on the cooler? |
| ☐ Yes | ☐ No | ☑ NA | 2. If custody seals were present, were they intact and unbroken? |

pH Strip ID: NA  Chlorine Strip ID: NA  Tested by: NA

Original temperature upon receipt / Derived (Corrected) temperature upon receipt  %Solid Snap-Cup ID: NA

2.4 / 2.4 °C  NA / NA °C  NA / NA °C  NA / NA °C

Method: ☑ Temperature Blank ☐ Against Bottles  IR Gun ID: 5  IR Gun Correction Factor: 0 °C

Method of coolant: ☑ Wet Ice ☐ Ice Packs ☐ Dry Ice ☐ None

| | | | |
|---|---|---|---|
| ☐ Yes | ☐ No | ☑ NA | 3. If temperature of any cooler exceeded 6.0°C, was Project Manager Notified? PM was Notified by: phone / email / face-to-face (circle one). |
| ☑ Yes | ☐ No | ☐ NA | 4. Is the commercial courier's packing slip attached to this form? |
| ☑ Yes | ☐ No | | 5. Were proper custody procedures (relinquished/received) followed? |
| ☑ Yes | ☐ No | | 6. Were sample IDs listed on the COC? |
| ☑ Yes | ☐ No | | 7. Were sample IDs listed on all sample containers? |
| ☑ Yes | ☐ No | | 8. Was collection date & time listed on the COC? |
| ☑ Yes | ☐ No | | 9. Was collection date & time listed on all sample containers? |
| ☑ Yes | ☐ No | | 10. Did all container label information (ID, date, time) agree with the COC? |
| ☑ Yes | ☐ No | | 11. Were tests to be performed listed on the COC? |
| ☑ Yes | ☐ No | | 12. Did all samples arrive in the proper containers for each test and/or in good condition (unbroken, lids on, etc.)? |
| ☑ Yes | ☐ No | | 13. Was adequate sample volume available? |
| ☐ Yes | ☑ No | | 14. Were all samples received within ½ the holding time or 48 hours, whichever comes first? |
| ☐ Yes | ☑ No | | 15. Were any samples containers missing/excess (circle one) samples Not listed on COC? |
| ☐ Yes | ☐ No | ☑ NA | 16. For VOA and RSK-175 samples, were bubbles present >"pea-size" (¼" or 6mm in diameter) in any of the VOA vials? |
| ☐ Yes | ☐ No | ☑ NA | 17. Were all DRO/metals/nutrient samples received at a pH of < 2? |
| ☐ Yes | ☐ No | ☑ NA | 18. Were all cyanide samples received at a pH > 12 and sulfide samples received at a pH > 9? |
| ☐ Yes | ☐ No | ☑ NA | 19. Were all applicable $NH_3$/TKN/cyanide/phenol/625.1/608.3 (< 0.5mg/L) samples free of residual chlorine? |
| ☐ Yes | ☐ No | ☑ NA | 20. Were client remarks/requests (i.e. requested dilutions, MS/MSD designations, etc...) correctly transcribed from the COC into the comment section in LIMS? |
| ☐ Yes | ☑ No | | 21. Was the quote number listed on the container label? If yes, Quote # NA |

**Sample Preservation** (Must be completed for any sample(s) incorrectly preserved or with headspace.)

Sample(s) NA _____ were received incorrectly preserved and were adjusted accordingly in sample receiving with NA mL of circle one: H2SO4, HNO3, HCl, NaOH using SR # NA.
Time of preservation NA. If more than one preservative is needed, please note in the comments below.

Sample(s) NA _____ were received with bubbles >6 mm in diameter.

Samples(s) NA _____ were received with TRC > 0.5 mg/L (If #19 is *no*) and were adjusted accordingly in sample receiving with sodium thiosulfate ($Na_2S_2O_3$) with Shealy ID: NA.

## Case Narrative
## Arcadis U.S., Inc.
### Lot Number: WI18011

This Report of Analysis contains the analytical result(s) for the sample(s) listed on the Sample Summary following this Case Narrative. The sample receiving date is documented in the header information associated with each sample.

All results listed in this report relate only to the samples that are contained within this report.

Sample receipt, sample analysis, and data review have been performed in accordance with the Pace Quality Assurance Management Plan (QAMP), applicable Shealy standard operating procedures (SOPs), the 2003 NELAC standard, and Shealy policies. Additionally, the DoD QSM version 5.3 has been followed for these samples, and specifically Table B-15 was followed for all PFAS samples. Any exceptions to the QAMP, SOPs, NELAC standards, the DoD QSM, or policies are qualified on the results page or discussed below.

All QC associated with these samples was in compliance with DOD QSM 5.3 table B-15 and our PFAS SOP.

Correction factors (CF) are used to calculate the original sample concentration. The CF is the inverse of the concentration factor (sample volume / extract final volume) times the dilution factor (DF). For undiluted analysis. For undiluted analysis, the extract is prepared for injection by adding 182 uL of sample extract + 8 uL of reagent water + 10 uL of internal standard solution to a polypropylene autosampler vial. An extra correction factor of 0.91 (182 uL / 200 uL = 0.91) applies. The CF is calculated as follows:

CF = DF * FV / Vo

FV is volume of extract (mL)
Vo is initial sample volume (mL)
DF is dilution factor. For undiluted analysis, DF = 1/0.91.

Sample concentration for aqueous samples:
Concentration (ng/L) = Cs*CF,

$$C_s = \frac{\left(\frac{(A_s x C_{is})}{A_{is}}\right) - B}{M1}$$

Where

$C_s$ is on column concentration of target analyte in the sample (ng/L)
$C_{is}$ is concentration of internal standard in the sample (ng/L)
$A_s$ is peak response of target analyte in the sample
$A_{is}$ is peak response of internal standard in the sample
M1 is the average RF from ICAL or the slope from linear regression ICAL
B is the y-intercept from the ICAL

Pace is a TNI accredited laboratory; however, the following analyses are currently not listed on our TNI scope of accreditation:

Biological Tissue: All, Non-Potable Water: SGT-HEM EPA 1664B, Silica EPA 200.7, Boron, Calcium, Silicon, Strontium EPA 200.8, Bicarbonate, Carbonate, and Hydroxide Alkalinity SM 2320 B-2011, Fecal Coliform SM 9221 C E-2006 & SM 9222D-2006, Strontium SW-846 6010D, VOC SM 6200 B-2011, Drinking Water: VOC (excluding BTEX, MTBE, Naphthalene, & 1,2-dichloroethane) EPA 524.2, Solid Chemical Material: TOC Walkley-Black.

Where applicable, all soil sample results (including LOQ and DL if requested) are corrected for dry weight unless flagged with a "W" qualifier.

If you have any questions regarding this report please contact the Pace Project Manager listed on the cover page.

LOQ = Limit of Quantitation
U = Not detected at or above the LOQ
H = Out of holding time
B = Detected in the method blank
N = Recovery is out of criteria
W = Reported on wet weight basis
E = Quantitation of compound exceeded the calibration range
P = The RPD between two GC columns exceeds 40%
LOD = Limit of Detection
DL = Detection Limit
J = Estimated result < LOQ and ≥ DL
Q = Surrogate failure
L = LCS/LCSD failure
S = MS/MSD failure

LOQ = Limit of Quantitation
U = Not detected at or above the LOQ
H = Out of holding time
B = Detected in the method blank
N = Recovery is out of criteria
W = Reported on wet weight basis
E = Quantitation of compound exceeded the calibration range
P = The RPD between two GC columns exceeds 40%
LOD = Limit of Detection
DL = Detection Limit
J = Estimated result < LOQ and ≥ DL
Q = Surrogate failure
L = LCS/LCSD failure
S = MS/MSD failure

LOQ = Limit of Quantitation
U = Not detected at or above the LOQ
H = Out of holding time
B = Detected in the method blank
N = Recovery is out of criteria
W = Reported on wet weight basis
E = Quantitation of compound exceeded the calibration range
P = The RPD between two GC columns exceeds 40%
LOD = Limit of Detection
DL = Detection Limit
J = Estimated result < LOQ and ≥ DL
Q = Surrogate failure
L = LCS/LCSD failure
S = MS/MSD failure

LOQ = Limit of Quantitation
U = Not detected at or above the LOQ
H = Out of holding time
B = Detected in the method blank
N = Recovery is out of criteria
W = Reported on wet weight basis
E = Quantitation of compound exceeded the calibration range
P = The RPD between two GC columns exceeds 40%
LOD = Limit of Detection
DL = Detection Limit
J = Estimated result < LOQ and ≥ DL
Q = Surrogate failure
L = LCS/LCSD failure
S = MS/MSD failure

LOQ = Limit of Quantitation
U = Not detected at or above the LOQ
H = Out of holding time
B = Detected in the method blank
N = Recovery is out of criteria
W = Reported on wet weight basis
E = Quantitation of compound exceeded the calibration range
P = The RPD between two GC columns exceeds 40%
LOD = Limit of Detection
DL = Detection Limit
J = Estimated result < LOQ and ≥ DL
Q = Surrogate failure
L = LCS/LCSD failure
S = MS/MSD failure

LOQ = Limit of Quantitation
U = Not detected at or above the LOQ
H = Out of holding time
B = Detected in the method blank
N = Recovery is out of criteria
W = Reported on wet weight basis
E = Quantitation of compound exceeded the calibration range
P = The RPD between two GC columns exceeds 40%
LOD = Limit of Detection
DL = Detection Limit
J = Estimated result < LOQ and ≥ DL
Q = Surrogate failure
L = LCS/LCSD failure
S = MS/MSD failure

LOQ = Limit of Quantitation
DL = Detection Limit
LOD = Limit of Detection

U = Not detected at or above the LOQ
J = Estimated result < LOQ and ≥ DL
* = RSD is out of criteria

N = Recovery is out of criteria
P = The RPD between two GC columns exceeds 40%
+ = RPD is out of criteria

Note: Calculations are performed before rounding to avoid round-off errors in calculated results

Issuing Authority: Pace ENV - WCOL

Revised: 9/29/2020

# Sample Receipt Checklist (SRC)

Client: PACE  Cooler Inspected by/date: JRG2 / 09/18/2021  Lot #: WI18011

Means of receipt: ☐ Pace ☐ Client ☐ UPS ☑ FedEx ☐ Other:

| | | | |
|---|---|---|---|
| ☐ Yes | ☑ No | | 1. Were custody seals present on the cooler? |
| ☐ Yes | ☐ No | ☑ NA | 2. If custody seals were present, were they intact and unbroken? |

pH Strip ID: NA  Chlorine Strip ID: NA  Tested by: NA

Original temperature upon receipt / Derived (Corrected) temperature upon receipt  %Solid Snap-Cup ID: 21-1928

3.1 / 3.1 °C  NA / NA °C  NA / NA °C  NA / NA °C

Method: ☑ Temperature Blank ☐ Against Bottles  IR Gun ID: 5  IR Gun Correction Factor: 0 °C

Method of coolant: ☑ Wet Ice ☐ Ice Packs ☐ Dry Ice ☐ None

| | | | |
|---|---|---|---|
| ☐ Yes | ☐ No | ☑ NA | 3. If temperature of any cooler exceeded 6.0°C, was Project Manager Notified? PM was Notified by: phone / email / face-to-face (circle one). |
| ☑ Yes | ☐ No | ☐ NA | 4. Is the commercial courier's packing slip attached to this form? |
| ☑ Yes | ☐ No | | 5. Were proper custody procedures (relinquished/received) followed? |
| ☑ Yes | ☐ No | | 6. Were sample IDs listed on the COC? |
| ☑ Yes | ☐ No | | 7. Were sample IDs listed on all sample containers? |
| ☑ Yes | ☐ No | | 8. Was collection date & time listed on the COC? |
| ☑ Yes | ☐ No | | 9. Was collection date & time listed on all sample containers? |
| ☑ Yes | ☐ No | | 10. Did all container label information (ID, date, time) agree with the COC? |
| ☑ Yes | ☐ No | | 11. Were tests to be performed listed on the COC? |
| ☑ Yes | ☐ No | | 12. Did all samples arrive in the proper containers for each test and/or in good condition (unbroken, lids on, etc.)? |
| ☑ Yes | ☐ No | | 13. Was adequate sample volume available? |
| ☐ Yes | ☑ No | | 14. Were all samples received within ½ the holding time or 48 hours, whichever comes first? |
| ☐ Yes | ☑ No | | 15. Were any samples containers missing/excess (circle one) samples Not listed on COC? |
| ☐ Yes | ☐ No | ☑ NA | 16. For VOA and RSK-175 samples, were bubbles present >"pea-size" (¼"or 6mm in diameter) in any of the VOA vials? |
| ☐ Yes | ☐ No | ☑ NA | 17. Were all DRO/metals/nutrient samples received at a pH of < 2? |
| ☐ Yes | ☐ No | ☑ NA | 18. Were all cyanide samples received at a pH > 12 and sulfide samples received at a pH > 9? |
| ☐ Yes | ☐ No | ☑ NA | 19. Were all applicable $NH_3$/TKN/cyanide/phenol/625.1/608.3 (< 0.5mg/L) samples free of residual chlorine? |
| ☐ Yes | ☐ No | ☑ NA | 20. Were client remarks/requests (i.e. requested dilutions, MS/MSD designations, etc…) correctly transcribed from the COC into the comment section in LIMS? |
| ☑ Yes | ☐ No | | 21. Was the quote number listed on the container label? If yes, Quote # 25221 |

**Sample Preservation** (Must be completed for any sample(s) incorrectly preserved or with headspace.)

Sample(s) NA were received incorrectly preserved and were adjusted accordingly in sample receiving with NA mL of circle one: H2SO4, HNO3, HCl, NaOH using SR # NA.
Time of preservation NA. If more than one preservative is needed, please note in the comments below.

Sample(s) NA were received with bubbles >6 mm in diameter.

Samples(s) NA were received with TRC > 0.5 mg/L. (If #19 is *no*) and were adjusted accordingly in sample receiving with sodium thiosulfate ($Na_2S_2O_3$) with Shealy ID: NA.

# Laboratory Endorsement

Sample analysis was performed in accordance with approved methodologies provided by the Environmental Protection Agency or other recognized agencies. The samples and their corresponding extracts will be maintained for a period of 30 days unless otherwise arranged. Following this retention period the samples will be disposed in accordance with Pace Gulf Coast's Standard Operating Procedures.

**Common Abbreviations that may be Utilized in this Report**

| | |
|---|---|
| **ND** | Indicates the result was Not Detected at the specified reporting limit |
| **NO** | Indicates the sample did not ignite when preliminary test performed for EPA Method 1030 |
| **DO** | Indicates the result was Diluted Out |
| **MI** | Indicates the result was subject to Matrix Interference |
| **TNTC** | Indicates the result was Too Numerous To Count |
| **SUBC** | Indicates the analysis was Sub-Contracted |
| **FLD** | Indicates the analysis was performed in the Field |
| **DL** | Detection Limit |
| **LOD** | Limit of Detection |
| **LOQ** | Limit of Quantitation |
| **RE** | Re-analysis |
| **CF** | HPLC or GC Confirmation |
| **00:01** | Reported as a time equivalent to 12:00 AM |

**Reporting Flags that may be Utilized in this Report**

| | |
|---|---|
| **J or I** | Indicates the result is between the MDL and LOQ |
| **J** | DOD flag on analyte in the parent sample for MS/MSD outside acceptance criteria |
| **U** | Indicates the compound was analyzed for but not detected |
| **B or V** | Indicates the analyte was detected in the associated Method Blank |
| **Q** | Indicates a non-compliant QC Result (See Q Flag Application Report) |
| ***** | Indicates a non-compliant or not applicable QC recovery or RPD – see narrative |
| **E** | Organics **-** The result is estimated because it exceeded the instrument calibration range |
| **E** | Metals - % diference for the serial dilution is > 10% |
| **L** | Reporting Limits adjusted to meet risk-based limit. |
| **P** | RPD between primary and confirmation result is greater than 40 |
| **DL** | Diluted analysis – when appended to Client Sample ID |

Sample receipt at Pace Gulf Coast is documented through the attached chain of custody. In accordance with NELAC, this report shall be reproduced only in full and with the written permission of Pace Gulf Coast. The results contained within this report relate only to the samples reported. The documented results are presented within this report.

This report pertains only to the samples listed in the Report Sample Summary and should be retained as a permanent record thereof. The results contained within this report are intended for the use of the client. Any unauthorized use of the information contained in this report is prohibited.

I certify that this data package is in compliance with The NELAC Institute (TNI) Standard 2009 and terms and conditions of the contract and Statement of Work both technically and for completeness, for other than the conditions in the case narrative. Release of the data contained in this hardcopy data package and in the computer readable data submitted has been authorized by the Quality Assurance Manager or his/her designee, as verified by the following signature.

Estimated uncertainty of measurement is available upon request. This report is in compliance with the DOD QSM as specified in the contract if applicable.

# Case Narrative

**Client:** Pace Analytical Services **Report:** 221101713

Pace Analytical Gulf Coast received and analyzed the sample(s) listed on the Report Sample Summary page of this report. Receipt of the sample(s) is documented by the attached chain of custody. This applies only to the sample(s) listed in this report. No sample integrity or quality control exceptions were identified unless noted below.

This report was completed in accordance with DOD QSM 5.3 as specified in the contract.

**No anomalies were found for the analyzed sample(s).**

RE: Project: WL27010-Revised Report
Pace Project No.: 10593493

Dear Kathy Smith:

Enclosed are the analytical results for sample(s) received by the laboratory on January 05, 2022. The results relate only to the samples included in this report. Results reported herein conform to the applicable TNI/NELAC Standards and the laboratory's Quality Manual, where applicable, unless otherwise noted in the body of the report.

The test results provided in this final report were generated by each of the following laboratories within the Pace Network:

- Pace Analytical Services - Minneapolis

This report was revised March 9, 2022, to report to the MDL.

If you have any questions concerning this report, please feel free to contact me.

Sincerely,

Kirsten Hogberg
kirsten.hogberg@pacelabs.com

# PROJECT NARRATIVE

Project: WL27010-Revised Report
Pace Project No.: 10593493

**Method:** **True TOF**
**Description:** Total Organofluorine
**Client:** Pace West Columbia,SC
**Date:** March 09, 2022

**General Information:**
7 samples were analyzed for True TOF by Pace Analytical Services Minneapolis. All samples were received in acceptable condition with any exceptions noted below or on the chain-of custody and/or the sample condition upon receipt form (SCUR) attached at the end of this report.

**Hold Time:**
The samples were analyzed within the method required hold times with any exceptions noted below.

**Method Blank:**
All analytes were below the report limit in the method blank, where applicable, with any exceptions noted below.

**Laboratory Control Spike:**
All laboratory control spike compounds were within QC limits with any exceptions noted below.

**Matrix Spikes:**
All percent recoveries and relative percent differences (RPDs) were within acceptance criteria with any exceptions noted below.

**Additional Comments:**

Analyte Comments:

QC Batch: 793374

N2: The lab does not hold NELAC/TNI accreditation for this parameter but other accreditations/certifications may apply. A complete list of accreditations/certifications is available upon request.

# QUALIFIERS

Project: WL27010-Revised Report
Pace Project No.: 10593493

## DEFINITIONS

DF - Dilution Factor, if reported, represents the factor applied to the reported data due to dilution of the sample aliquot.

ND - Not Detected at or above adjusted reporting limit.

TNTC - Too Numerous To Count

J - Estimated concentration above the adjusted method detection limit and below the adjusted reporting limit.

MDL - Adjusted Method Detection Limit.

PQL - Practical Quantitation Limit.

RL - Reporting Limit - The lowest concentration value that meets project requirements for quantitative data with known precision and bias for a specific analyte in a specific matrix.

S - Surrogate

1,2-Diphenylhydrazine decomposes to and cannot be separated from Azobenzene using Method 8270. The result for each analyte is a combined concentration.

Consistent with EPA guidelines, unrounded data are displayed and have been used to calculate % recovery and RPD values.

LCS(D) - Laboratory Control Sample (Duplicate)

MS(D) - Matrix Spike (Duplicate)

DUP - Sample Duplicate

RPD - Relative Percent Difference

NC - Not Calculable.

SG - Silica Gel - Clean-Up

U - Indicates the compound was analyzed for, but not detected.

N-Nitrosodiphenylamine decomposes and cannot be separated from Diphenylamine using Method 8270. The result reported for each analyte is a combined concentration.

Reported results are not rounded until the final step prior to reporting. Therefore, calculated parameters that are typically reported as "Total" may vary slightly from the sum of the reported component parameters.

Pace Analytical is TNI accredited. Contact your Pace PM for the current list of accredited analytes.

TNI - The NELAC Institute.

## ANALYTE QUALIFIERS

| | |
|---|---|
| N2 | The lab does not hold NELAC/TNI accreditation for this parameter but other accreditations/certifications may apply. A complete list of accreditations/certifications is available upon request. |

# Laboratory Endorsement

Sample analysis was performed in accordance with approved methodologies provided by the Environmental Protection Agency or other recognized agencies. The samples and their corresponding extracts will be maintained for a period of 30 days unless otherwise arranged. Following this retention period the samples will be disposed in accordance with Pace Gulf Coast's Standard Operating Procedures.

**Common Abbreviations that may be Utilized in this Report**

| | |
|---|---|
| **ND** | Indicates the result was Not Detected at the specified reporting limit |
| **NO** | Indicates the sample did not ignite when preliminary test performed for EPA Method 1030 |
| **DO** | Indicates the result was Diluted Out |
| **MI** | Indicates the result was subject to Matrix Interference |
| **TNTC** | Indicates the result was Too Numerous To Count |
| **SUBC** | Indicates the analysis was Sub-Contracted |
| **FLD** | Indicates the analysis was performed in the Field |
| **DL** | Detection Limit |
| **LOD** | Limit of Detection |
| **LOQ** | Limit of Quantitation |
| **RE** | Re-analysis |
| **CF** | HPLC or GC Confirmation |
| **00:01** | Reported as a time equivalent to 12:00 AM |

**Reporting Flags that may be Utilized in this Report**

| | |
|---|---|
| **J or I** | Indicates the result is between the MDL and LOQ |
| **J** | DOD flag on analyte in the parent sample for MS/MSD outside acceptance criteria |
| **U** | Indicates the compound was analyzed for but not detected |
| **B or V** | Indicates the analyte was detected in the associated Method Blank |
| **Q** | Indicates a non-compliant QC Result (See Q Flag Application Report) |
| ***** | Indicates a non-compliant or not applicable QC recovery or RPD – see narrative |
| **E** | Organics **-** The result is estimated because it exceeded the instrument calibration range |
| **E** | Metals - % diference for the serial dilution is > 10% |
| **L** | Reporting Limits adjusted to meet risk-based limit. |
| **P** | RPD between primary and confirmation result is greater than 40 |
| **DL** | Diluted analysis – when appended to Client Sample ID |

Sample receipt at Pace Gulf Coast is documented through the attached chain of custody. In accordance with NELAC, this report shall be reproduced only in full and with the written permission of Pace Gulf Coast. The results contained within this report relate only to the samples reported. The documented results are presented within this report.

This report pertains only to the samples listed in the Report Sample Summary and should be retained as a permanent record thereof. The results contained within this report are intended for the use of the client. Any unauthorized use of the information contained in this report is prohibited.

I certify that this data package is in compliance with The NELAC Institute (TNI) Standard 2009 and terms and conditions of the contract and Statement of Work both technically and for completeness, for other than the conditions in the case narrative. Release of the data contained in this hardcopy data package and in the computer readable data submitted has been authorized by the Quality Assurance Manager or his/her designee, as verified by the following signature.

Estimated uncertainty of measurement is available upon request. This report is in compliance with the DOD QSM as specified in the contract if applicable.

# Case Narrative

**Client:** Pace Analytical Services **Report:** 222010533

Pace Analytical Gulf Coast received and analyzed the sample(s) listed on the Report Sample Summary page of this report. Receipt of the sample(s) is documented by the attached chain of custody. This applies only to the sample(s) listed in this report. No sample integrity or quality control exceptions were identified unless noted below.

This report was completed in accordance with DOD QSM 5.3 as specified in the contract.

**SEMI-VOLATILES MASS SPECTROMETRY**

Samples 22201053301 (CMT-VRTB-01-1_12172021), 22201053302 (CMT-VRTB-01-2_12172021) and 22201053303 (CMT-VRTB-01-3_12172021) were re-extracted outside holding time for contamination of PFBA and PFPeA in the oxidation reagent blank. In addition, 22201053301 (CMT-VRTB-01-1_12172021) did not appear to fully oxidize due to the presence of 6:2FTS at the same concentration in the Pre and Post Top Assay analysis. Both data sets are being reported

Samples 22201053304 (CMT-VRTB-01-4_12172021), 22201053305 (CMT-VRTB-01-5_12172021), 22201053306 (CMT-VRTB-01-6_12172021) and 22201053307 (CMT-VRTB-01-7_12172021) were re-extracted outside holding time due to contamination in the oxidation blank greater than the reporting limit for compounds PFBA, PFPeA and PFHxA.

Sample 22201053306 (CMT-VRTB-01-6_12172021) was re-extracted outside holding time due to extracted internal standard failure associated with target compound PFBA. The re-extracted analysis was within control limits

In the PFAS Top Assay QSM B15 (Post) analysis, the recovery for the extracted internal standard MPFBA is outside the control limits for sample 22201053303 (CMT-VRTB-01-3_12172021) .

In the PFAS Top Assay QSM B15 (Post) analysis, the recovery for the extracted internal standard MPFBA is outside the control limits for sample 22201053304 (CMT-VRTB-01-4_12172021) .

In the PFAS Top Assay QSM B15 (Post) analysis, the recovery for the extracted internal standard MPFBA is outside the control limits for sample 22201053307 (CMT-VRTB-01-7_12172021) .

# Manual Integrations

Manual Integrations for LC and IC (if performed) are documented in the raw data.
No other manual integrations were performed by Pace Gulf Coast.

## Case Narrative
## Arcadis U.S., Inc.
### Lot Number: WL27010

This Report of Analysis contains the analytical result(s) for the sample(s) listed on the Sample Summary following this Case Narrative. The sample receiving date is documented in the header information associated with each sample.

All results listed in this report relate only to the samples that are contained within this report. Where sampling is conducted by the client, results relate to the accuracy of the information provided, and as the samples are received.

Sample receipt, sample analysis, and data review have been performed in accordance with the most current approved The NELAC Institute (TNI) standards, the Pace Analytical Services, LLC ("Pace") Laboratory Quality Manual, standard operating procedures (SOPs), and Pace policies. Additionally, the DoD QSM version 5.3 has been followed for these samples, and specifically Table B-15 was followed for all PFAS samples. Any exceptions to the TNI standards, the Laboratory Quality Manual, SOPs, the DoD QSM, or policies are qualified on the results page or discussed below.

Pace is a TNI accredited laboratory; however, the following analyses are currently not listed on our TNI scope of accreditation: Drinking Water: VOC (excluding BTEX, MTBE, Naphthalene, & 1,2-dichloroethane) EPA 524.2, E. coli and Total coliforms SM 9223 B-2004, Solid Chemical Material: TOC Walkley-Black, Biological Tissue: All, Non-Potable Water: SGT-HEM EPA 1664B, Silica EPA 200.7, Boron, Calcium, Silicon, Strontium EPA 200.8, Bicarbonate, Carbonate, and Hydroxide Alkalinity SM 2320 B-2011, SM 9221 C E-2006 & SM 9222D-2006, Strontium SW-846 6010D, VOC SM 6200 B-2011, Fecal Coliform Colilert-18.

If you have any questions regarding this report, please contact the Pace Project Manager listed on the cover page.

LOQ = Limit of Quantitation
U = Not detected at or above the LOQ
H = Out of holding time
B = Detected in the method blank
N = Recovery is out of criteria
W = Reported on wet weight basis
E = Quantitation of compound exceeded the calibration range
P = The RPD between two GC columns exceeds 40%
LOD = Limit of Detection
DL = Detection Limit
J = Estimated result < LOQ and ≥ DL
Q = Surrogate failure
L = LCS/LCSD failure
S = MS/MSD failure

LOQ = Limit of Quantitation
U = Not detected at or above the LOQ
H = Out of holding time
B = Detected in the method blank
N = Recovery is out of criteria
W = Reported on wet weight basis
E = Quantitation of compound exceeded the calibration range
P = The RPD between two GC columns exceeds 40%
LOD = Limit of Detection
DL = Detection Limit
J = Estimated result < LOQ and ≥ DL
Q = Surrogate failure
L = LCS/LCSD failure
S = MS/MSD failure

# Sample Receipt Checklist (SRC)

Client: Arcadis  Cooler inspected by/date: KDRW / 12/27/2021  Lot #: WL27010

Means of receipt: ☐ Pace ☐ Client ☐ UPS ☑ FedEx ☐ Other: _____

| | | | |
|---|---|---|---|
| ☐ Yes | ☑ No | | 1. Were custody seals present on the cooler? |
| ☐ Yes | ☐ No | ☑ NA | 2. If custody seals were present, were they intact and unbroken? |

pH Strip ID: NA  Chlorine Strip ID: NA  Tested by: NA

Original temperature upon receipt / Derived (Corrected) temperature upon receipt  %Solid Snap-Cup ID: NA

5.0 / 5.0 °C  3.0 / 3.6 °C  NA / NA °C  NA / NA °C

Method: ☑ Temperature Blank ☐ Against Bottles  IR Gun ID: 6  IR Gun Correction Factor: 0 °C

Method of coolant: ☑ Wet Ice ☐ Ice Packs ☐ Dry Ice ☐ None

| | | | |
|---|---|---|---|
| ☐ Yes | ☐ No | ☑ NA | 3. If temperature of any cooler exceeded 6.0°C, was Project Manager Notified? PM was Notified by: phone / email / face-to-face (circle one). |
| ☑ Yes | ☐ No | ☐ NA | 4. Is the commercial courier's packing slip attached to this form? |
| ☑ Yes | ☐ No | | 5. Were proper custody procedures (relinquished/received) followed? |
| ☑ Yes | ☐ No | | 6. Were sample IDs listed on the COC? |
| ☑ Yes | ☐ No | | 7. Were sample IDs listed on all sample containers? |
| ☑ Yes | ☐ No | | 8. Was collection date & time listed on the COC? |
| ☑ Yes | ☐ No | | 9. Was collection date & time listed on all sample containers? |
| ☑ Yes | ☐ No | | 10. Did all container label information (ID, date, time) agree with the COC? |
| ☑ Yes | ☐ No | | 11. Were tests to be performed listed on the COC? |
| ☑ Yes | ☐ No | | 12. Did all samples arrive in the proper containers for each test and/or in good condition (unbroken, lids on, etc.)? _____ |
| ☑ Yes | ☐ No | | 13. Was adequate sample volume available? |
| ☐ Yes | ☑ No | | 14. Were all samples received within ½ the holding time or 48 hours, whichever comes first? |
| ☐ Yes | ☑ No | | 15. Were any samples containers missing/excess (circle one) samples Not listed on COC? |
| ☐ Yes | ☐ No | ☑ NA | 16. For VOA and RSK-175 samples, were bubbles present >"pea-size" (¼"or 6mm in diameter) in any of the VOA vials? |
| ☐ Yes | ☐ No | ☑ NA | 17. Were all DRO/metals/nutrient samples received at a pH of < 2? |
| ☐ Yes | ☐ No | ☑ NA | 18. Were all cyanide samples received at a pH > 12 and sulfide samples received at a pH > 9? |
| ☐ Yes | ☐ No | ☑ NA | 19. Were all applicable $NH_3$/TKN/cyanide/phenol/625.1/608.3 (< 0.5mg/L) samples free of residual chlorine? |
| ☐ Yes | ☐ No | ☑ NA | 20. Were client remarks/requests (i.e. requested dilutions, MS/MSD designations, etc…) correctly transcribed from the COC into the comment section in LIMS? |
| ☑ Yes | ☐ No | | 21. Was the quote number listed on the container label? If yes, Quote # 25221 |

**Sample Preservation** (Must be completed for any sample(s) incorrectly preserved or with headspace.)

Sample(s) NA were received incorrectly preserved and were adjusted accordingly in sample receiving with NA mL of circle one: H2SO4, HNO3, HCl, NaOH using SR # NA.

Time of preservation: NA. If more than one preservative is needed, please note in the comments below.

Sample(s) NA were received with bubbles >6 mm in diameter.

Samples(s) NA were received with TRC > 0.5 mg/L (If #19 is ***no***) and were adjusted accordingly in sample receiving with sodium thiosulfate ($Na_2S_2O_3$) with Shealy ID: NA.

SR barcode labels applied by: KDRW Date: 12/27/2021

## Case Narrative
## Arcadis U.S., Inc.
### Lot Number: WL30065

This Report of Analysis contains the analytical result(s) for the sample(s) listed on the Sample Summary following this Case Narrative. The sample receiving date is documented in the header information associated with each sample.

All results listed in this report relate only to the samples that are contained within this report.

Sample receipt, sample analysis, and data review have been performed in accordance with the Pace Quality Assurance Management Plan (QAMP), applicable Shealy standard operating procedures (SOPs), the 2003 NELAC standard, and Shealy policies. Additionally, the DoD QSM version 5.3 has been followed for these samples, and specifically Table B-15 was followed for all PFAS samples. Any exceptions to the QAMP, SOPs, NELAC standards, the DoD QSM, or policies are qualified on the results page or discussed below.

All QC associated with these samples was in compliance with DOD QSM 5.3 table B-15 and our PFAS SOP.

Correction factors (CF) are used to calculate the original sample concentration. The CF is the inverse of the concentration factor (sample volume / extract final volume) times the dilution factor (DF). For undiluted analysis. For undiluted analysis, the extract is prepared for injection by adding 182 uL of sample extract + 8 uL of reagent water + 10 uL of internal standard solution to a polypropylene autosampler vial. An extra correction factor of 0.91 (182 uL / 200 uL = 0.91) applies. The CF is calculated as follows:

CF = DF * FV / Vo

FV is volume of extract (mL)
Vo is initial sample volume (mL)
DF is dilution factor. For undiluted analysis, DF = 1/0.91.

Sample concentration for aqueous samples:
Concentration (ng/L) = Cs*CF,

$$C_s = \frac{\left(\frac{(A_s x C_{is})}{A_{is}}\right) - B}{M1}$$

Where

$C_s$ is on column concentration of target analyte in the sample (ng/L)
$C_{is}$ is concentration of internal standard in the sample (ng/L)
$A_s$ is peak response of target analyte in the sample
$A_{is}$ is peak response of internal standard in the sample
M1 is the average RF from ICAL or the slope from linear regression ICAL
B is the y-intercept from the ICAL

Pace is a TNI accredited laboratory; however, the following analyses are currently not listed on our TNI scope of accreditation: Drinking Water: VOC (excluding BTEX, MTBE, Naphthalene, & 1,2-dichloroethane) EPA 524.2, E. coli and Total coliforms SM 9223 B-2004, Solid Chemical Material: TOC Walkley-Black, Biological Tissue: All, Non-Potable Water: SGT-HEM EPA 1664B, Silica EPA 200.7, Boron, Calcium, Silicon, Strontium EPA 200.8, Bicarbonate, Carbonate, and Hydroxide Alkalinity SM 2320 B-2011, SM 9221 C E-2006 & SM 9222D-2006, Strontium SW-846 6010D, VOC SM 6200 B-2011, Fecal Coliform Colilert-18.

If you have any questions regarding this report, please contact the Pace Project Manager listed on the cover page.

For sample WL30065-020, sample matrix prevented full volume from being extracted, precluding method mandated bottle rinse. Elution solvent was aliquoted directly into the reservoir, rinsing the inside. Surrogate recovery may be adversely affected.

Surrogate recovery for the following samples was outside control limits: WL30065-005, WL30065-006, WL30065-007, WL30065-008, WL30065-020. Evidence of matrix interference is present; therefore, re-extraction and/or re-analysis was not performed.

The MS/MSD associated with sample WL30065-006 had multiple compounds recovered outside of the acceptance limits. The LCS was recovered within the required acceptance limits; therefore, this demonstrates a matrix effect and data quality is not impacted.

LOQ = Limit of Quantitation
U = Not detected at or above the LOQ
H = Out of holding time
B = Detected in the method blank
N = Recovery is out of criteria
W = Reported on wet weight basis
E = Quantitation of compound exceeded the calibration range
P = The RPD between two GC columns exceeds 40%
LOD = Limit of Detection
DL = Detection Limit
J = Estimated result < LOQ and ≥ DL
Q = Surrogate failure
L = LCS/LCSD failure
S = MS/MSD failure

LOQ = Limit of Quantitation
U = Not detected at or above the LOQ
H = Out of holding time
B = Detected in the method blank
N = Recovery is out of criteria
W = Reported on wet weight basis
E = Quantitation of compound exceeded the calibration range
P = The RPD between two GC columns exceeds 40%
LOD = Limit of Detection
DL = Detection Limit
J = Estimated result < LOQ and ≥ DL
Q = Surrogate failure
L = LCS/LCSD failure
S = MS/MSD failure

LOQ = Limit of Quantitation
U = Not detected at or above the LOQ
H = Out of holding time
B = Detected in the method blank
N = Recovery is out of criteria
W = Reported on wet weight basis
E = Quantitation of compound exceeded the calibration range
P = The RPD between two GC columns exceeds 40%
LOD = Limit of Detection
DL = Detection Limit
J = Estimated result < LOQ and ≥ DL
Q = Surrogate failure
L = LCS/LCSD failure
S = MS/MSD failure

LOQ = Limit of Quantitation
U = Not detected at or above the LOQ
H = Out of holding time
B = Detected in the method blank
N = Recovery is out of criteria
W = Reported on wet weight basis
E = Quantitation of compound exceeded the calibration range
P = The RPD between two GC columns exceeds 40%
LOD = Limit of Detection
DL = Detection Limit
J = Estimated result < LOQ and ≥ DL
Q = Surrogate failure
L = LCS/LCSD failure
S = MS/MSD failure

LOQ = Limit of Quantitation
U = Not detected at or above the LOQ
H = Out of holding time
B = Detected in the method blank
N = Recovery is out of criteria
W = Reported on wet weight basis
E = Quantitation of compound exceeded the calibration range
P = The RPD between two GC columns exceeds 40%
LOD = Limit of Detection
DL = Detection Limit
J = Estimated result < LOQ and ≥ DL
Q = Surrogate failure
L = LCS/LCSD failure
S = MS/MSD failure

LOQ = Limit of Quantitation
U = Not detected at or above the LOQ
H = Out of holding time
B = Detected in the method blank
N = Recovery is out of criteria
W = Reported on wet weight basis
E = Quantitation of compound exceeded the calibration range
P = The RPD between two GC columns exceeds 40%
LOD = Limit of Detection
DL = Detection Limit
J = Estimated result < LOQ and ≥ DL
Q = Surrogate failure
L = LCS/LCSD failure
S = MS/MSD failure

# Sample Receipt Checklist (SRC)

Client: Arcadis  Cooler Inspected by/date: JRG2 / 12/30/2021  Lot #: WL33065

Means of receipt: ☐ Pace ☐ Client ☐ UPS ☑ FedEx ☐ Other:

| | | | |
|---|---|---|---|
| ☐ Yes | ☑ No | | 1. Were custody seals present on the cooler? |
| ☐ Yes | ☐ No | ☑ NA | 2. If custody seals were present, were they intact and unbroken? |

pH Strip ID: NA  Chlorine Strip ID: NA  Tested by: NA

Original temperature upon receipt / Derived (Corrected) temperature upon receipt  %Solid Snap-Cup ID: NA

8.8 / 8.8 °C  NA / NA °C  NA / NA °C  NA / NA °C

Method: ☐ Temperature Blank ☑ Against Bottles  IR Gun ID: 5  IR Gun Correction Factor: 0 °C

Method of coolant: ☐ Wet Ice ☑ Ice Packs ☐ Dry Ice ☐ None

| | | | |
|---|---|---|---|
| ☑ Yes | ☐ No | ☐ NA | 3. If temperature of any cooler exceeded 6.0°C, was Project Manager Notified? PM was Notified by: phone (email) face-to-face (circle one). |
| ☑ Yes | ☐ No | ☐ NA | 4. Is the commercial courier's packing slip attached to this form? |
| ☑ Yes | ☐ No | | 5. Were proper custody procedures (relinquished/received) followed? |
| ☑ Yes | ☐ No | | 6. Were sample IDs listed on the COC? |
| ☑ Yes | ☐ No | | 7. Were sample IDs listed on all sample containers? |
| ☑ Yes | ☐ No | | 8. Was collection date & time listed on the COC? |
| ☑ Yes | ☐ No | | 9. Was collection date & time listed on all sample containers? |
| ☑ Yes | ☐ No | | 10. Did all container label information (ID, date, time) agree with the COC? |
| ☑ Yes | ☐ No | | 11. Were tests to be performed listed on the COC? |
| ☑ Yes | ☐ No | | 12. Did all samples arrive in the proper containers for each test and/or in good condition (unbroken, lids on, etc.)? |
| ☑ Yes | ☐ No | | 13. Was adequate sample volume available? |
| ☐ Yes | ☑ No | | 14. Were all samples received within ½ the holding time or 48 hours, whichever comes first? |
| ☐ Yes | ☑ No | | 15. Were any samples containers missing/excess (circle one) samples Not listed on COC? |
| ☐ Yes | ☐ No | ☑ NA | 16. For VOA and RSK-175 samples, were bubbles present >"pea-size" (¼"or 6mm in diameter) in any of the VOA vials? |
| ☐ Yes | ☐ No | ☑ NA | 17. Were all DRO/metals/nutrient samples received at a pH of < 2? |
| ☐ Yes | ☐ No | ☑ NA | 18. Were all cyanide samples received at a pH > 12 and sulfide samples received at a pH > 9? |
| ☐ Yes | ☐ No | ☑ NA | 19. Were all applicable $NH_3$/TKN/cyanide/phenol/625.1/608.3 (< 0.5mg/L) samples free of residual chlorine? |
| ☐ Yes | ☐ No | ☑ NA | 20. Were client remarks/requests (i.e. requested dilutions, MS/MSD designations, etc…) correctly transcribed from the COC into the comment section in LIMS? |
| ☐ Yes | ☑ No | | 21. Was the quote number listed on the container label? If yes, Quote # |

**Sample Preservation** (Must be completed for any sample(s) incorrectly preserved or with headspace.)

Sample(s) NA were received incorrectly preserved and were adjusted accordingly in sample receiving with NA mL of circle one: H2SO4, HNO3, HCl, NaOH using SR # NA. Time of preservation NA. If more than one preservative is needed, please note in the comments below.

Sample(s) NA were received with bubbles >6 mm in diameter.

Samples(s) NA were received with TRC > 0.5 mg/L (If #19 is ***no***) and were adjusted accordingly in sample receiving with sodium thiosulfate ($Na_2S_2O_3$) with Shealy ID: NA.

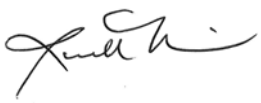
# Laboratory Endorsement

Sample analysis was performed in accordance with approved methodologies provided by the Environmental Protection Agency or other recognized agencies. The samples and their corresponding extracts will be maintained for a period of 30 days unless otherwise arranged. Following this retention period the samples will be disposed in accordance with Pace Gulf Coast's Standard Operating Procedures.

**Common Abbreviations that may be Utilized in this Report**

| | |
|---|---|
| **ND** | Indicates the result was Not Detected at the specified reporting limit |
| **NO** | Indicates the sample did not ignite when preliminary test performed for EPA Method 1030 |
| **DO** | Indicates the result was Diluted Out |
| **MI** | Indicates the result was subject to Matrix Interference |
| **TNTC** | Indicates the result was Too Numerous To Count |
| **SUBC** | Indicates the analysis was Sub-Contracted |
| **FLD** | Indicates the analysis was performed in the Field |
| **DL** | Detection Limit |
| **LOD** | Limit of Detection |
| **LOQ** | Limit of Quantitation |
| **RE** | Re-analysis |
| **CF** | HPLC or GC Confirmation |
| **00:01** | Reported as a time equivalent to 12:00 AM |

**Reporting Flags that may be Utilized in this Report**



| | |
|---|---|
| **J or I** | Indicates the result is between the MDL and LOQ |
| **J** | DOD flag on analyte in the parent sample for MS/MSD outside acceptance criteria |
| **U** | Indicates the compound was analyzed for but not detected |
| **B or V** | Indicates the analyte was detected in the associated Method Blank |
| **Q** | Indicates a non-compliant QC Result (See Q Flag Application Report) |
| ***** | Indicates a non-compliant or not applicable QC recovery or RPD – see narrative |
| **E** | Organics **-** The result is estimated because it exceeded the instrument calibration range |
| **E** | Metals - % diference for the serial dilution is > 10% |
| **L** | Reporting Limits adjusted to meet risk-based limit. |
| **P** | RPD between primary and confirmation result is greater than 40 |
| **DL** | Diluted analysis – when appended to Client Sample ID |

Sample receipt at Pace Gulf Coast is documented through the attached chain of custody. In accordance with NELAC, this report shall be reproduced only in full and with the written permission of Pace Gulf Coast. The results contained within this report relate only to the samples reported. The documented results are presented within this report.

This report pertains only to the samples listed in the Report Sample Summary and should be retained as a permanent record thereof. The results contained within this report are intended for the use of the client. Any unauthorized use of the information contained in this report is prohibited.

I certify that this data package is in compliance with The NELAC Institute (TNI) Standard 2009 and terms and conditions of the contract and Statement of Work both technically and for completeness, for other than the conditions in the case narrative. Release of the data contained in this hardcopy data package and in the computer readable data submitted has been authorized by the Quality Assurance Manager or his/her designee, as verified by the following signature.

Estimated uncertainty of measurement is available upon request. This report is in compliance with the DOD QSM as specified in the contract if applicable.

# Case Narrative

**Client:** Pace Analytical Services **Report:** 222041920

Pace Analytical Gulf Coast received and analyzed the sample(s) listed
on the Report Sample Summary page of this report. Receipt of the sample(s) is documented
by the attached chain of custody. This applies only to the sample(s) listed in this report.
No sample integrity or quality control exceptions were identified unless noted below.

**SEMI-VOLATILES MASS SPECTROMETRY**

In the PFAS Top Assay QSM B15 (Pre) analysis, the recovery for the extracted internal standard M2 6:2 FTS is above the upper control limits for sample 22204192001 (CMT-VRTB-01_7_04152022) . There are no target hits for the associated compounds.

# Sample Summary

## Case Narrative
## Arcadis U.S., Inc.
### Lot Number: XD16001

This Report of Analysis contains the analytical result(s) for the sample(s) listed on the Sample Summary following this Case Narrative. The sample receiving date is documented in the header information associated with each sample.

All results listed in this report relate only to the samples that are contained within this report.

Sample receipt, sample analysis, and data review have been performed in accordance with the Pace Quality Assurance Management Plan (QAMP), applicable Shealy standard operating procedures (SOPs), the 2003 NELAC standard, and Shealy policies. Additionally, the DoD QSM version 5.3 has been followed for these samples, and specifically Table B-15 was followed for all PFAS samples. Any exceptions to the QAMP, SOPs, NELAC standards, the DoD QSM, or policies are qualified on the results page or discussed below.

All QC associated with these samples was in compliance with DOD QSM 5.3 table B-15 and our PFAS SOP.

Correction factors (CF) are used to calculate the original sample concentration. The CF is the inverse of the concentration factor (sample volume / extract final volume) times the dilution factor (DF). For undiluted analysis. For undiluted analysis, the extract is prepared for injection by adding 182 uL of sample extract + 8 uL of reagent water + 10 uL of internal standard solution to a polypropylene autosampler vial. An extra correction factor of 0.91 (182 uL / 200 uL = 0.91) applies. The CF is calculated as follows:

CF = DF * FV / Vo

FV is volume of extract (mL)
Vo is initial sample volume (mL)
DF is dilution factor. For undiluted analysis, DF = 1/0.91.

Sample concentration for aqueous samples:
Concentration (ng/L) = Cs*CF,

$$C_s = \frac{\left(\frac{(A_s x C_{is})}{A_{is}}\right) - B}{M1}$$

Where

$C_s$ is on column concentration of target analyte in the sample (ng/L)
$C_{is}$ is concentration of internal standard in the sample (ng/L)
$A_s$ is peak response of target analyte in the sample
$A_{is}$ is peak response of internal standard in the sample
M1 is the average RF from ICAL or the slope from linear regression ICAL
B is the y-intercept from the ICAL

Pace is a TNI accredited laboratory; however, the following analyses are currently not listed on our TNI scope of accreditation: Drinking Water: VOC (excluding BTEX, MTBE, Naphthalene, & 1,2-dichloroethane) EPA 524.2, E. coli and Total coliforms SM 9223 B-2004, Solid Chemical Material: TOC Walkley-Black, Biological Tissue: All, Non-Potable Water: SGT-HEM EPA 1664B, Silica EPA 200.7, Boron, Calcium, Silicon, Strontium EPA 200.8, Bicarbonate, Carbonate, and Hydroxide Alkalinity SM 2320 B-2011, SM 9221 C E-2006 & SM 9222D-2006, Strontium SW-846 6010D, VOC SM 6200 B-2011, Fecal Coliform Colilert-18.

If you have any questions regarding this report, please contact the Pace Project Manager listed on the cover page.

For sample XD16001-011 sample matrix prevented full volume from being extracted, precluding method mandated bottle rinse. Elution solvent was aliquoted directly into the reservoir, rinsing the inside. Surrogate recovery may be adversely affected.

Surrogate recovery for the following sample(s) was outside control limits: XD16001-008, XD16001-010, XD16001-011, XD16001-012. Evidence of matrix interference is present; therefore, re-extraction and/or re-analysis was not performed.

The laboratory control sample (LCS) and / or laboratory control sample duplicate (LCSD) for analytical batch 39067 exceeded acceptance criteria for the following analytes: 6:2 FTS.

The MS/MSD associated with samples XD16001-002, XD16001-015 had compounds recovered outside of the acceptance limits. The LCS was recovered within the required acceptance limits; therefore, this demonstrates a matrix effect and data quality is not impacted.

LOQ = Limit of Quantitation
U = Not detected at or above the LOQ
H = Out of holding time
B = Detected in the method blank
N = Recovery is out of criteria
W = Reported on wet weight basis
E = Quantitation of compound exceeded the calibration range
P = The RPD between two GC columns exceeds 40%
LOD = Limit of Detection
DL = Detection Limit
J = Estimated result < LOQ and ≥ DL
Q = Surrogate failure
L = LCS/LCSD failure
S = MS/MSD failure

LOQ = Limit of Quantitation
U = Not detected at or above the LOQ
H = Out of holding time
B = Detected in the method blank
N = Recovery is out of criteria
W = Reported on wet weight basis
E = Quantitation of compound exceeded the calibration range
P = The RPD between two GC columns exceeds 40%
LOD = Limit of Detection
DL = Detection Limit
J = Estimated result < LOQ and ≥ DL
Q = Surrogate failure
L = LCS/LCSD failure
S = MS/MSD failure

LOQ = Limit of Quantitation
U = Not detected at or above the LOQ
H = Out of holding time
B = Detected in the method blank
N = Recovery is out of criteria
W = Reported on wet weight basis
E = Quantitation of compound exceeded the calibration range
P = The RPD between two GC columns exceeds 40%
LOD = Limit of Detection
DL = Detection Limit
J = Estimated result < LOQ and ≥ DL
Q = Surrogate failure
L = LCS/LCSD failure
S = MS/MSD failure

LOQ = Limit of Quantitation
U = Not detected at or above the LOQ
H = Out of holding time
B = Detected in the method blank
N = Recovery is out of criteria
W = Reported on wet weight basis
E = Quantitation of compound exceeded the calibration range
P = The RPD between two GC columns exceeds 40%
LOD = Limit of Detection
DL = Detection Limit
J = Estimated result < LOQ and ≥ DL
Q = Surrogate failure
L = LCS/LCSD failure
S = MS/MSD failure

LOQ = Limit of Quantitation
B = Detected in the method blank
E = Quantitation of compound exceeded the calibration range
DL = Detection Limit
Q = Surrogate failure
U = Not detected at or above the LOQ
N = Recovery is out of criteria
P = The RPD between two GC columns exceeds 40%
J = Estimated result < LOQ and ≥ DL
L = LCS/LCSD failure
H = Out of holding time
W = Reported on wet weight basis
LOD = Limit of Detection
S = MS/MSD failure
