RSLs	Regional Screening Levels
SCTL	Soil Cleanup Target Levels
SPLP	Synthetic Precipitation Leaching Procedure
TCE	Trichloroethene
TCLP	Toxicity Characteristic Leaching Procedure
UMI	United Metals, Inc.
VOCs	Volatile Organic Compounds

# **Executive Summary**

The 175-acre United Metals, Inc. (UMI) Superfund site (the Site) is located in a rural area about 1,000 feet east of Highway 71 and about 3 miles south of Interstate 1-10 in Marianna, Jackson County, Florida. Battery recycling operations took place on the Site between 1979 and 1991. Operations consisted of cutting the tops off batteries, separating the lead plates from the plastic casings, crushing and pelletizing the casings, and sending them off site for further processing. Facility activities also included the discharge of wastewater to an unlined holding pond via a concrete-lined trench. In the early 1990s, the Florida Department of Environmental Protection (FDEP) determined that these activities resulted in contamination of soil, sediment and ground water with heavy metals. The United States Environmental Protection Agency (EPA) placed the Site on the Superfund program's National Priorities List (NPL) on April 30, 2003.

EPA selected a remedy to address the Site's contamination in a 2006 Record of Decision (ROD) and updated the remedy with an Explanation of Significant Differences (ESD) in September 2010. The final selected remedy consisted of monitored natural attenuation (MNA) of contaminated ground water; excavation, solidification and capping of contaminated soils and sediment; and the implementation of institutional controls. After completion of remedy construction, EPA issued the Site's Preliminary Close Out Report (PCOR) on September 14, 2011. Ground water monitoring will continue until cleanup goals are met.

This is the first Five-Year Review (FYR) for the Site. The triggering action for this FYR was the on-site construction start date of the remedial action on October 14, 2009.

The remedy at the Site is protective of human health and the environment in the short term. Contaminated soils and sediment were excavated, treated and contained in a capped monolith. The cap prevents potential exposure to contaminants of concern (COCs) in surface soils and sediment and helps prevent contaminants from leaching into the ground water below. Additionally, institutional controls protect the integrity of the monolith and further limit the potential of contaminant exposure by prohibiting digging in areas of remaining soil contamination under building foundations and restricting ground water use. In general, ground water sampling results indicate that ground water quality at the Site has improved since the soil remedial action; this improvement is expected to continue. However, in order for the remedy to be protective in the long term, more information and data is necessary for manganese in the surficial and Floridan aquifers to determine if additional actions are necessary, including monitoring wells and/or institutional controls.

# First Five-Year Review Report for United Metals, Inc. Superfund Site

### **1.0 Introduction**

The purpose of a five-year review (FYR) is to evaluate the implementation and performance of a remedy in order to determine if the remedy will continue to be protective of human health and the environment. FYR reports document FYR methods, findings and conclusions. In addition, FYR reports identify issues found during the review, if any, and document recommendations to address them.

EPA prepares FYRs pursuant to the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) Section 121 and the National Oil and Hazardous Substances Pollution Contingency Plan (NCP). CERCLA Section 121 states:

If the President selects a remedial action that results in any hazardous substances, pollutants, or contaminants remaining at the site, the President shall review such remedial action no less often than each 5 years after the initiation of such remedial action to assure that human health and the environment are being protected by the remedial action being implemented. In addition, if upon such review it is the judgment of the President that action is appropriate at such site in accordance with section [104] or [106], the President shall take or require such action. The President shall report to the Congress a list of facilities for which such review is required, the results of all such reviews, and any actions taken as a result of such reviews.

EPA interpreted this requirement further in the NCP, 40 Code of Federal Regulations (CFR) Section 300.430(f)(4)(ii), which states:

If a remedial action is selected that results in hazardous substances, pollutants, or contaminants remaining at the site above levels that allow for unlimited use and unrestricted exposure, the lead agency shall review such action no less often than every five years after initiation of the selected remedial action.

Skeo Solutions, an EPA Region 4 contractor, conducted the FYR and prepared this report regarding the remedy implemented at the United Metals, Inc. Superfund site (the Site) in Marianna, Jackson County, Florida. EPA's contractor conducted this FYR from March to October 2014. EPA is the lead agency for developing and implementing the remedy for the Superfund-financed cleanup at the Site. The Florida Department of Environmental Protection (FDEP), as the support agency representing the State of Florida, has reviewed all supporting documentation and provided input to EPA during the FYR process.

This is the first FYR for the Site. The triggering action for this statutory review is the on-site construction start date of the remedial action. The FYR is required because hazardous substances, pollutants or contaminants remain at the Site above levels that allow for unlimited use and unrestricted exposure. The Site consists of one operable unit.

# 2.0 Site Chronology

Table 1 lists the dates of important events for the Site.

### 3.0 Background

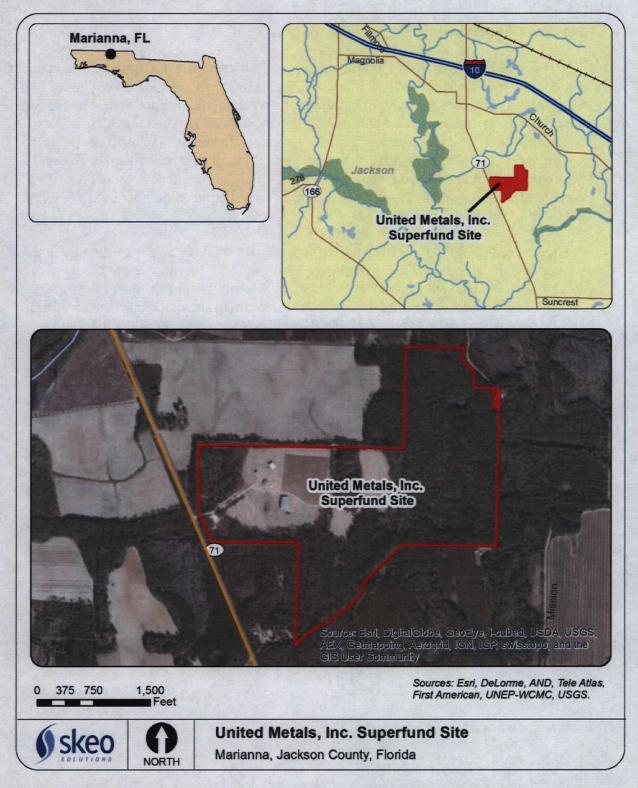

#### 3.1 **Physical Characteristics**

The 175-acre Site is located in a rural area about 1,000 feet east of Highway 71 and about 3 miles south of Interstate 1-10 in Marianna, Jackson County, Florida (See Figure 1). The Site currently includes a shed, two buildings and a rectangular capped area. The capped area is 5.6 acres and the fenced area around the capped area is 6.3 acres. A chain-link fence surrounds the capped area (Figure 2). Original site features included two unlined holding ponds, a battery processing facility, truck shop, plastic pellet plant, office and health center building (Appendix J). In February 2013, the Cumbaa Family Trust 1995 purchased the two parcels that make up the site property (parcel number 06-3N-09-0000-0060-0010).

A large agricultural field borders the Site to the north. Woodlands border the Site to the south and east. Woodlands and a portion of Highway 71 border the Site to the west. Wetlands are located about 700 feet south of the Site and 1,000 feet east of the eastern fenceline of the former UMI facility area. An intermittent stream connects the wetlands and flows west-southwest to the Chipola River. The Chipola River is about 1.5 miles west of the Site. An unoccupied residence is about 1,600 feet northwest of the Site.

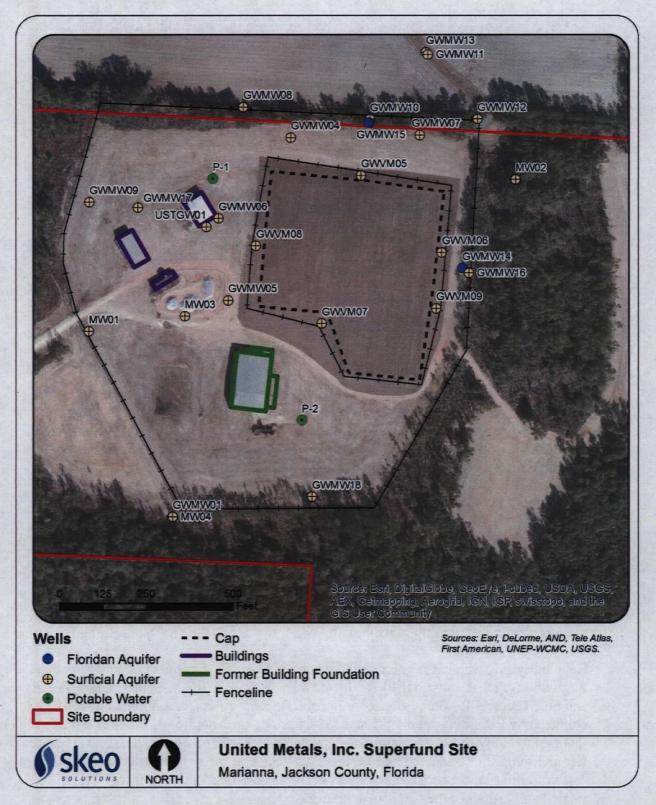

The Site is fairly level and has an average elevation of 100 feet above mean sea level. The property is located in the Marianna River Valley Lowlands physiographic province. Surface soils are generally sandy and underlain by clays. Sinkhole formation in the Site area is prevalent. The ground water occurs in two aquifer systems at the Site. The surficial aquifer system consists of sand, sandy clay, clayey sand and clay. The thickness of the surficial aquifer averages about 40 feet at the Site. The Floridan Aquifer system is separated from the surficial aquifer system by a clayey semi-confining unit. The Floridan Aquifer system (Suwannee Limestone) is generally 50 to 60 feet below land surface in the site area. There is a ground water divide east of the former battery recycling building. The surficial ground water generally flows to the west on the western side of the divide and to the east on the eastern side of the divide. Near the Site, ground water in the Floridan Aquifer flows to the west and southwest, where it discharges to the Chipola River.

Disclaimer: This map and any boundary lines within the map are approximate and subject to change. The map is not a survey. The map is for informational purposes only regarding EPA's response actions at the Site.

#### 3.2 Land and Resource Use

The Site is about 7 miles south of the center of Marianna. According to the U.S. Census Bureau, the City of Marianna had a population of about 9,000 people in 2013. The area around the Site is sparsely populated and is primarily agricultural and wooded. Battery recycling occurred on the Site between 1979 and 1991. The former battery recycling operations area occupies about 24 acres. The former operations area includes a 6.3-acre fenced area, which includes a 5.6-acre capped area that is unused. The rest of the site property is zoned for light residential development. The current tenant leases the Site for auto-scrapping operations. The tenant also leases roll-off storage containers, which are stored on site. All site use activities occur outside of the fenced, capped area.

The Floridan Aquifer system is the primary source of potable water and irrigation water in Jackson County. Most residents in the area rely on private wells for potable water. There are two wells on the Site that were previously used to provide production water for facility operations. According to the 2011 remedial action report, a previous property owner who resided on the Site obtained drinking water from one of these production wells; this well is installed in the Floridan Aquifer. Uses of the nearby Chipola River include recreational fishing, swimming and boating.

#### 3.3 History of Contamination

Construction of the battery recycling facility began in September 1979 and operations began in November 1979. The UMI facility primarily recycled lead-acid batteries, but the facility also recycled nickel-cadmium batteries. Operations included cutting the tops off batteries and separating the lead plates from the plastic casings. Additional processing activities included crushing and pelletizing the plastic battery casings and sending them to an off-site extruding facility. Operations also included transporting the lead components and lead oxide from the batteries to an off-site lead smelting facility.

The liquid in the batteries drained to a reservoir and flowed through a channel in the floor to a series of concrete basins. Facility operators used lime to neutralize the wastewater in the basins. The lead-oxide residues were precipitated for reclamation. The wastewater then flowed from the concrete basins to an unlined holding pond east of the recycling operations building via a concrete-lined trench. It was reported that some of the wastewater flowed directly to the holding pond, bypassing the concrete settling basins.

Regulatory involvement began in 1980 when the Florida Department of Environmental Regulation (FDER, now FDEP) conducted a Hazardous Waste Inspection of the facility and noted several Resource Conservation and Recovery Act (RCRA) violations. Data collected by FDER between 1981 and 1984 from on-site monitoring wells determined that facility activities had contaminated ground water with cadmium, lead and arsenic. Off-site sampling conducted by FDER during May and June of 1981 detected metal concentrations above background levels in a drainage ditch under Highway 71, immediately south of the UMI site entrance.

Between 1986 and 1991, EPA and FDER investigations determined that site activities also resulted in the contamination of holding pond sediment and surface water with high concentrations of lead, copper and zinc.

#### 3.4 Initial Response

Following the 1980 FDER site inspection, in 1981 UMI entered into a Consent Order with FDER to address the operational and pollution concerns noted during the inspection. In June 1983, UMI completed the construction of a closed-loop wastewater treatment system, removed contaminated soils and sediments from the drainage ditch and holding pond, and implemented a limited ground water monitoring program. UMI stored the excavated soil and sediment from the pond and ditch in the on-site Materials Storage Building (Appendix J shows historical building locations). In June 1984, FDER determined that UMI met the requirements of the Consent Order.

EPA conducted an inspection in July 1986 and found numerous RCRA violations. Violations noted during the EPA inspection included improper closure of the holding pond, improper storage of hazardous waste, improper ground water monitoring, and operation of a hazardous waste storage and treatment facility without a permit.

In 1989, UMI sold the property to Anrich. Anrich renovated the process area, installed new pollution control devices and conducted limited battery reclaiming operations at the Site. In 1991, FDER conducted another Hazardous Waste Inspection of the facility and noted several violations, including storage of a hazardous waste pile without a permit and unapproved transportation of hazardous waste to Taiwan. Anrich ceased operations at the Site in July 1991 and notified FDER shortly thereafter that it had ceased doing business in the United States.

FDEP conducted a site investigation in June 1993 and an expanded site investigation in December 1994. Sampling results confirmed that site activities resulted in the contamination of soil, sediment and ground water with heavy metals. Sampling detected the highest surface soil lead concentrations north of the Battery Recycling Building, south of the plastic pellet plant, in the drainage ditch leading to Highway 71, and in the drainage ditch along Highway 71 (see Appendix J for historical site feature locations). Sampling also detected elevated concentrations of chromium, iron, manganese, nickel and zinc.

The results of the expanded site investigation led to a limited removal action by EPA in 1996. Cleanup activities included the removal and proper disposal of six 55-gallon drums of hazardous waste found on site. EPA also solidified and disposed of several hundred gallons of sulfuric acid sludge discovered in a 6,000-gallon tank on the Site.

ÈPA placed the Site on the National Priorities List in April 2003 and conducted another removal action at the Site in summer 2006. Activities included the separation of the 2,500-cubic yard waste pile, previously stored in the Materials Storage Building, into soil and debris. EPA disposed of the hazardous waste debris at a hazardous waste landfill and treated the remaining hazardous soil. Rendered non-hazardous by treatment, EPA disposed of the soil at an off-site landfill. This material represented the principal threat to human health and the environment, and the greatest potential source for ground water contamination.

#### 3.5 Basis for Taking Action

EPA conducted a remedial investigation of the Site in three phases. EPA conducted the primary remedial investigation in June and July 2002, followed by a supplemental remedial investigation in December 2003, and an additional remedial investigation sampling event in March 2005. EPA completed the Site's combined remedial investigation/feasibility study in December 2005.

The Site's risk assessment, which was completed in May 2005 and included in the remedial investigation, identified the former lead battery recycling operation as the primary source of site contamination. The primary release mechanisms were spills and poor housekeeping in the battery processing areas and discharges to the unlined holding ponds (see Appendix J for historical site feature locations). Truck traffic and stormwater runoff spread the contamination throughout the Site, to Highway 71 and the ditches that line it.

The remedial investigation determined that surface soil contamination was generally confined to the facility boundary as defined by the fenceline (the outer fenceline depicted in Figure 2), but there was also contamination west and southwest of the fenceline. The investigation identified lead, antimony and arsenic as the most significant surface soil contaminants. Subsurface soil contamination was less widespread than surface soil contaminants in the subsurface soils.

The remedial investigation identified lead as the most significant contaminant in site sediments. The highest level of soil/sediment contamination was found in the ditches that border the site access road west of the former operations area. Lesser but significant contamination was found along Highway 71 north and south of the access road and downstream of the drainage ditch that empties into a wetland west of Highway 71.

The remedial investigation determined that ground water contamination appeared to be confined to part of the surficial aquifer immediately downgradient of the battery plant, especially near the unlined waste pond. The investigation found no evidence that contamination had spread to the underlying Floridan Aquifer. The investigation also determined that the two potable water wells on the Site and the six residential wells on properties around the Site were installed in the deeper Floridan Aquifer. Remedial investigation sampling detected several constituents in the potable water samples. However, none exceeded maximum contaminant levels (MCLs). Based on this assessment, EPA determined that the potable ground water wells were not impacted by site contamination.

In 2005, the risk assessment identified visitors and trespassers as the only receptors for potential exposure to surface soil and sediment contamination via ingestion, dermal contact or inhalation of particulates. The risk assessment found no risk of contaminant exposure to workers due to the lack of a worker population in the contaminated area.

Under a future residential redevelopment scenario, EPA found unacceptable risk from exposure to contaminants in site soils and ingestion of drinking water from a future onsite well installed in the surficial aquifer.

Ċ

### 4.0 Remedial Actions

In accordance with CERCLA and the NCP, the overriding goals for any remedial action are protection of human health and the environment and compliance with applicable or relevant and appropriate requirements (ARARs). A number of remedial alternatives were considered for the Site, and final selection was made based on an evaluation of each alternative against nine evaluation criteria that are specified in Section 300.430(e)(9)(iii) of the NCP. The nine criteria are:

- 1. Overall Protection of Human Health and the Environment
- 2. Compliance with ARARs
- 3. Long-Term Effectiveness and Permanence
- 4. Reduction of Toxicity, Mobility or Volume through Treatment
- 5. Short-Term Effectiveness
- 6. Implementability
- 7. Cost
- 8. State Acceptance
- 9. Community Acceptance

#### 4.1 Remedy Selection

EPA selected a remedy to address soil, sediment and ground water contamination in the Site's September 2006 Record of Decision (ROD). The ROD listed the following remedial action objectives (RAOs):

Soil and Sediment

- Prevent ingestion, inhalation or direct contact with surface soil that contains concentrations above the remedial goals (RGs).
- Control migration and leaching of contaminants in surface and subsurface soil to ground water that could result in ground water contamination above MCLs or health-based remedial goals.
- Prevent ingestion or inhalation of sediment particulates in air that contain concentrations above the RGs.
- Protect the wetlands environment and its biota from exposure to contaminants above RGs.
- Permanently and/or significantly reduce the mobility/toxicity/volume of hazardous waste with treatment.
- Control future releases of contaminants to ensure protection of human health and the environment.

#### Ground Water

- Prevent ingestion of ground water with contaminant concentrations above RGs.
- Restore the ground water aquifer system by cleanup to the RGs.
- Prevent migration of pollutants beyond the known contaminant plume or established point of compliance.

- Control future releases of contaminants of concern to ground water to ensure protection of human health and the environment.
- Permanently or significantly reduce the mobility/toxicity/volume of characteristic principal-threat hazardous waste with treatment.

The selected remedy, as stated in the ROD, consisted of:

- Decontamination (as appropriate) and demolition of the Battery Plant and Materials Storage buildings and other site structures and buildings as necessary.
- Recycling of metal debris.
- Excavation and stockpiling of contaminated soil and sediment.
- Ex situ stabilization and solidification of contaminated soil and sediments and possibly concrete building debris.
- Additional excavation necessary to create a sitewide disposal area.
- Backfill of clean soil into areas outside the fenceline where contaminated soil and sediment were removed.
- Compaction and disposal of waste (treated soil/sediment and possibly concrete building debris), assuming a 20 percent increase in soil/sediment volume due to stabilization/solidification into the on-site disposal cell.
- Installation of a geosynthetic clay liner over the treated material in the disposal cell.
- Installation of a 1.5-foot clean soil cover over the disposal site.
- Installation of a 6-inch topsoil cover and grass seeding over the disposal cell and soil/sediment excavation area.
- Restoration of the remediated wetlands.
- Institutional controls to protect the long-term integrity of the monolith, such as a restrictive covenant that limits on-site land use activities to those consistent with the remedy and engineering controls to limit access, such as fencing. Institutional controls will also restrict the installation of irrigation or potable wells in the area of the contaminant plume without the notification and approval of EPA and FDEP.
- Implementation of monitored natural attenuation (MNA) or other ground water monitoring system until the ground water RGs are met. In situ treatment of contaminated ground water via injection of treatment additives at selected monitoring wells may be implemented if 1) ground water contaminants do not decline to concentrations below the State of Florida's Chapter 62-777 Florida Administrative Code natural attenuation default criteria in a reasonable time following completion of the soil remedy; 2) ground water contamination is determined to be migrating past the present known extent of the plume; or 3) the contaminant plume is not attenuating at an acceptable rate of decline or has reached asymptotic levels.

On September 10, 2010, EPA signed an Explanation of Significant Differences (ESD), amending two components of the selected remedy. The ROD stated that the 36 milligrams per kilogram (mg/kg) lead ecological cleanup value was a "not-to-exceed" concentration in the RG table. The ESD clarified that the 36 mg/kg lead concentration is

an average concentration for the purpose of the ecological cleanup, rather than a "not-toexceed" value. The ESD also provided an explanation for elevated antimony concentrations allowed in the Synthetic Precipitation Leaching Procedure (SPLP) leachate from stabilized/solidified contaminated soil. See section 4.2 for additional information.

The ROD derived site cleanup goals from the human health risk assessment and ARARs. The ROD based soil cleanup goals on a cancer risk of  $1 \times 10^{-6}$  and a non-cancer hazard quotient of 1 using residential exposure assumptions. According to the ROD, soil cleanup goals calculated for protection from direct exposure and ingestion of soil applied to the first two feet of soil. The soil cleanup goals for prevention of contaminants of concern (COCs) leaching to ground water applied to the entire soil column, to the top of the ground water table. The ecological cleanup goals for protection of terrestrial biota from soil and aquatic biota from sediment applied to the top 6 inches of soil and sediment.

The ROD based ground water cleanup goals on federal and state MCLs, and if not available, a cancer risk of  $1 \times 10^{-6}$  and a non-cancer hazard index of 1, using residential exposure assumptions.

Table 2 presents cleanup goals and COCs for soil, sediment and ground water.

ČÔĊ	Cleanup Goal <sup>a</sup>	Basis <sup>a</sup>
Soil		
Arsenic	2.1 mg/kg	Direct contact
Īron	23,400 mg/kg	Direct contact
Manganese	3,500 mg/kg	Direct contact
Lead	400 mg/kg	Direct contact
Antimony	31 mg/kg	Direct contact
Lead	400 mg/kg	Migration to ground water
Antimony	5.4 mg/kg	Migration to ground water
Çadmium	7.5 mg/kg	Migration to ground water
Lead	500 mg/kg	Ecological protection
Sediment	•	
Lead	36 mg/kg	Ecological protection
Ground Water		
Aluminum	15,643 µg/L	HQ = 1
Antimony	6 µg/L	FL MCL
Cadmium	5 μg/L	FL MCL
Iron	4,700 μg/L	HQ = 1
Lead	15 μg/L	FL MCL
Manganese	375 μg/L	$\overline{HQ} = 1$
Vanadium	36 µg/L	HQ = 1
Trichloroethene	3 µg/L	FL MCL
a) Cleanup goals as defin	ed in the 2006 ROD	
mg/kg – Milligrams per l		
µg/L – Micrograms per l	iter	
HQ - Hazard quotient	<u>.</u>	<u></u>

#### Table 2: Soil, Sediment and Ground Water Cleanup Goals

#### 4.2 Remedy Implementation

EPA began the Site's remedial design on September 28, 2006, and completed it on September 29, 2008. In August 2009, EPA received \$7.4 million through the American Recovery and Reinvestment Act to assist with cleanup costs. Project mobilization began on October 14, 2009, for the site clearing and site preparation work. Mobilization occurred on December 1, 2009, for the decontamination and demolition of the former battery plant and storage building. On February 8, 2010, mobilization began for the fullscale remedial action implementation of soil excavation, cell construction, soil treatment, capping, monitoring well construction and site restoration.

During the remedial action, EPA excavated 43,324 cubic yards of soil and treated about 61,985 tons of soil and sediment. The debris from the screening process was treated with 5 percent Portland cement and sampled for toxicity characteristic leaching procedure (TCLP) metals and SPLP analysis. If samples failed the TCLP analysis, EPA added 2.5 percent Portland cement and re-sampled. Based on the results of the TCLP testing, EPA shipped about 1,215 tons of stabilized debris, considered non-hazardous waste, to an off-site landfill. EPA shipped the remaining 1,890 cubic yards of contaminated debris to a hazardous waste landfill.

EPA performed confirmatory sampling to ensure the treated soil and sediment met the standards set for the stabilization of soil at the Site. After excavation and/or treatment, EPA placed the soil and sediment in a containment cell (monolith).

Antimony was the only metal that consistently failed SPLP testing. Treatability studies indicated that antimony concentrations in leachate from treated soil may exceed the SPLP performance standard ( $6 \mu g/L$ ) established in the ROD. EPA determined that finding a soil stabilization formula to lower the antimony concentrations in the leachate was technically infeasible and would compromise the formulation's ability to achieve all other stabilization specifications. EPA explained this variance in the 2010 ESD.

EPA also performed confirmatory sampling in the excavated areas. EPA compared analytical results to RGs for direct contact and migration to ground water. In most locations, results from confirmatory sampling met the cleanup goals. Exceptions included the side walls at the northeast corner and west side of the foundation/concrete slab of the Plastics Building and the northeast corner and east side of the foundation/concrete slab of the Office Building. Following excavation, lead concentrations in those areas still exceeded RGs. According to the September 2011 remedial action report, lead concentrations in those excavated areas ranged from 420 mg/kg to 3,130 mg/kg, which are above the RG of 400 mg/kg. Additional excavation was not considered feasible as it would compromise the integrity of the structures and foundations. Following excavation, those areas were backfilled with clean fill, effectively eliminating the potential exposure pathway for direct contact to the contaminated soil. EPA implemented institutional controls for those areas to prevent potential contaminant exposure. For a detailed description of these institutional controls, see Section 6.3, Institutional Control Review.

The property owner entered into a Declaration of Restrictive Covenants with FDEP on August 22, 2013. The restrictive covenant restricts land and ground water use on the two parcels that make up the Site. See section 6.3 for a detailed discussion of the Site's institutional controls.

Remedial investigation sampling identified the highest wetland sediment lead concentrations (as high as 13,000 mg/kg) in the top six inches of wetland sediment. Based on this finding, the ROD identified truck traffic and surface water runoff from the main operational area of the Site as the likely mechanisms for the spread of contamination to the wetland area. Lead concentrations below the 6-inch depth ranged from 7 mg/kg to 109 mg/kg. The ROD stated that the 36 mg/kg lead ecological cleanup value was a "not-to-exceed" concentration. However, the ESD clarified that the 36 mg/kg lead concentration is an average concentration for the purpose of the ecological cleanup, rather than a "not-to-exceed" value. Therefore, EPA remediated the wetland area across from the Site by removing the top six inches of sediment and backfilling the area with clean topsoil. EPA also re-planted about 500 dogwoods in the wetland area.

EPA installed new monitoring wells at the Site to further characterize the ground water and provide performance monitoring of stabilized soils in the monolith. EPA ground water sampling in October 2010 and May 2011 verified the natural attenuation of the Site's ground water contaminants. Based on these results, EPA determined that the optional in situ ground water treatment included in the ROD was not necessary. Installation of the new monitoring wells and development and sampling of all preexisting site monitoring wells were the only actions required for construction of the ground water remedy. Ground water monitoring will continue until all cleanup goals have been met for two consecutive years.

EPA performed a pre-final site inspection on October 14, 2010, and a final site inspection on June 21, 2011. FDEP took over operation and maintenance of the soil remedy including the containment cell and monolith on June 21, 2012. Following the completion of remedy construction, EPA issued the Site's Preliminary Close Out Report (PCOR) on September 14, 2011.

#### 4.3 Operation and Maintenance (O&M)

The Site's 2010 O&M Plan (revised in February 2012) establishes the Site's O&M requirements. General components of the remedy addressed in the O&M Plan include:

- Inspection of installed remedial systems and integrity of monitoring wells;
- Maintenance of the installed remedial systems and final cover over the monolith;
- Ground water monitoring for performance and natural attenuation;
- Site security for protection of the remedial systems; and
- Documentation of enforcement of deed restrictions applied to the Site.

Following the completion of soil remediation, EPA's long-term response action (LTRA) contractor, Black & Veatch Special Projects Corp. (Black & Veatch), conducted quarterly ground water monitoring from December 2010 through October 2012, and semi-annual monitoring thereafter.

FDEP's O&M contractor, TetraTech, performs all other site O&M activities. According to quarterly site inspection reports, O&M activities include cap inspections for erosion, settlement and evidence of animal intrusion, as well as inspections of monitoring wells, fencing and vegetation in the restored wetland and ditch areas. TetraTech performs quarterly O&M inspections. The Site's O&M Plan states the specific inspection schedules for each O&M item. FDEP plans to have the cap mowed four times per year, from the spring through the fall. FDEP will adjust the mowing schedule as needed. The site tenant mows the area outside of the cap. FDEP also has a separate "Critical Response" task assignment that it can use to check or respond to the facility after a major storm or hurricane.

The ROD estimated annual O&M costs for the soil and sediment remedy of \$23,750 over 30 years. The ROD estimated annual O&M costs for the ground water remedy of \$66,200 over 30 years. Table 3 displays LTRA and some O&M costs for the Site between 2010 and 2014. Annual LTRA costs are currently in line with or lower than the estimated costs. The change in ground water monitoring frequency from quarterly to semi-annually provides a significant cost savings, as evidenced by the O&M costs for 2012 and 2013. The quarterly O&M costs for 2014 are \$446.

	Annual LTRA Cost	Annual O&M Cost
2010	\$100,000	NA
2011	\$100,000	NA
2012	\$50,000	NA
2013	\$50,000	NA ·
2014	NA	\$892ª

#### Table 3: Annual O&M Costs

# 5.0 Progress Since the Last Five-Year Review

# This is the Site's first FYR.

.23

### 6.0 Five-Year Review Process

#### 6.1 Administrative Components

EPA Region 4 initiated the FYR in March 2014 and scheduled its completion for October 2014. The EPA remedial project manager (RPM) Joe Alfano led the EPA site review team, which also included the EPA community involvement coordinator L'Tonya Spencer and contractor support provided to EPA by Skeo Solutions. The review schedule established consisted of the following activities:

- Community notification.
- Document review.
- Data collection and review.
- Site inspection.
- Local interviews.
- FYR Report development and review.

#### 6.2 Community Involvement

In April 2014, EPA published a public notice in the *Jackson County Floridan* newspaper announcing the commencement of the FYR process for the Site, providing contact information for the EPA RPM and CIC and inviting community participation. The press notice is available in Appendix B. No one contacted EPA as a result of the advertisement.

EPA will make the final FYR Report available to the public. Upon completion of the FYR, EPA will place copies of the document in the designated site repository: Jackson County Public Library at 2929 Green Street, Marianna, Florida 32446.

#### 6.3 Document Review

#### ARARs Review

CERCLA Section 121(d)(1) requires that Superfund remedial actions attain "a degree of cleanup of hazardous substance, pollutants, and contaminants released into the environment and of control of further release at a minimum which assures protection of human health and the environment." The remedial action must achieve a level of cleanup that at least attains those requirements that are legally applicable or relevant and appropriate.

• Applicable requirements are those cleanup standards, standards of control and other substantive requirements, criteria or limitations promulgated under federal environmental, state environmental or facility siting laws that specifically address a hazardous substance, remedial action, location or other circumstance found at a CERCLA site.

- Relevant and appropriate requirements are those standards that, while not "applicable," address problems or situations sufficiently similar to those encountered at the CERCLA site that their use is well suited to the particular site. Only those state standards more stringent than federal requirements may be applicable or relevant and appropriate.
- To-Be-Considered criteria are non-promulgated advisories and guidance that are not legally binding, but should be considered in determining the necessary remedial action. For example, To-Be-Considered criteria may be particularly useful in determining health-based levels where no ARARs exist or in developing the appropriate method for conducting a remedial action.

Chemical-specific ARARs are health- or risk-based numerical values or methodologies which, when applied to site-specific conditions, result in the establishment of numerical values. These values establish an acceptable amount or concentration of a chemical that may remain in, or discharged to, the ambient environment. Examples of chemicalspecific ARARs include maximum contaminant levels (MCLs) under the federal Safe Drinking Water Act and ambient water quality criteria enumerated under the federal Clean Water Act.

Action-specific ARARs are technology- or activity-based requirements or limits on actions taken with respect to a particular hazardous substance. These requirements are triggered by a particular remedial activity, such as discharge of contaminated ground water or in-situ remediation.

Location-specific ARARs are restrictions on hazardous substances or the conduct of the response activities solely based on their location in a special geographic area. Examples include restrictions on activities in wetlands, sensitive habitats and historic places.

Remedial actions are required to comply with the chemical-specific ARARs identified in the ROD. In performing the FYR for compliance with ARARs, only those ARARs that address the protectiveness of the remedy are reviewed.

#### Ground Water ARARs

According to the 2006 ROD, the ground water ARARs for the eight ground water COCs are the National Primary Drinking Water Standards and Florida Drinking Water Standards. This FYR compared current federal and Florida MCLs to the 2006 ARARs for the Site's ground water COCs. The ARARs associated with the Site's ground water have not changed since 2006 (Table 4).

COCª	2006 ROD ARARs (µg/L)	Current ARARs (µg/L) <sup>b</sup>	ARAR Changes
Aluminum	NA°	NA°	NA
Antimony	6	6	None
Cadmium	5	5	None
Iron	NA°	NA°	NA
Lead	15 <sup>d</sup>	15 <sup>d</sup>	None
Manganese	NA°	NA°	NA
Vanadium	NA°	NA°	NA
Trichloroethene	3	3	None

## Table 4: Previous and Current ARARs for Ground Water COCs

Water MCLs is <u>http://water.epa.gov/drink/contaminants/</u> (accessed on 03/17/2014). State standards are based on Florida State Primary Drinking Water MCLs:

http://www.dep.state.fl.us/water/drinkingwater/standard.htm (accessed on 03/17/2014).

c) ARAR not identified in ROD. Cleanup goal based on risk.

d) Lead is regulated by a treatment technique that requires systems to control the corrosiveness of their water. If more than 10 percent of tap water samples exceed the action level, water systems must take additional steps. 15 μg/L is the Action Level for lead.
 μg/L – Micrograms per liter

## Soil and Sediment ARARs

The 2006 ROD did not establish chemical-specific ARARs for the soil or sediment COCs. Action-specific soil and sediment ARARs specified in the 2006 ROD were relevant during the remedy's construction, but are not relevant to the remedy's continued protectiveness. See Section 7.2 for a discussion of soil cleanup goals and any changes in toxicity levels for COCs.

# Institutional Control Review

The ROD requires the implementation of land use and ground water use restrictions for the Site. The purpose of these institutional controls is to prevent human exposure to contamination above site cleanup goals and to ensure the long-term integrity of the monolith.

The property owner entered into a Declaration of Restrictive Covenants with FDEP on August 22, 2013. The restrictive covenant states that no one will dig into, excavate or otherwise disturb the capped monolith without first notifying and obtaining approval from EPA and FDEP, and that no one will construct any ground water wells on the restricted portions of the Site or use the shallow ground water for any purpose without receiving written prior approval from EPA and FDEP. EPA based the institutional control boundary for surficial ground water on a November 2011 plume map (Appendix I). The restrictive covenant also established "do not disturb" areas under portions of the former office and plastic pellet plant building foundations. The covenant restricts any activities that could disturb the soil in those areas (Figure 3). The restrictive covenant applies to the two site parcels owned by Cumbaa Family Trust 1995 (see Figure 3). Surficial ground water contamination above RGs extends across the two site parcels and a third parcel to the north of the Site. FDEP has not enacted a restrictive covenant limiting ground water use on this northern property. Ground water monitoring wells located on the northern property routinely have manganese concentrations above RGs (Appendix F). However, EPA is coordinating with the Northwest Florida Water Management District to restrict future well placement on the northern property. EPA considers this an adequate institutional control for the ground water plume on the northern property.

There are two potable water wells, P-1 and P-2, installed in the Floridan Aquifer on the Site. The Site's remedial investigation determined that these wells were not impacted by site contamination. According to the 2011 remedial action report, ground water use is not restricted for these wells. The 2011 remedial action report also states that the previous site tenant used P-1 for drinking water. According to the Site's remedial investigation report, P-2 is not connected to an electrical power line. P-1 can be used by the current site occupants for potable water. As deep ground water at the Site flows toward the west/southwest, P-1 is immediately downgradient of the capped monolith (Figure 4). EPA sampled both wells repeatedly in 2010. Data indicates that the wells have not been impacted by site-related contamination.

Remedial investigation findings in 2002 determined that residential wells near the Site are installed in the Floridan Aquifer and are not impacted by site contamination. COC concentrations were all below MCLs during remedial investigation sampling of these wells. However, manganese has been consistently detected above RGs in the Floridan Aquifer wells (GWMW14 and GWMW15) since sampling began in 2010. EPA will continue to evaluate manganese in the Floridan Aquifer to determine if additional actions are needed in the future. The nearest residential well is located about 1,600 feet northwest of the Site; the well's pump was previously dismantled and is no longer in use.

In March 2014, Skeo staff conducted research on the Jackson County Clerk's Office website and found the deed restrictive covenant information pertaining to the Site listed in Table 5.

Date	Type of Document	Description	Book #	Page #
04/23/2012	Warranty Deed	Transfer of site property ownership from Faircloth Properties, Inc. to the Cumbaa Family Trust 1995.	1346	0156
02/01/2013	Warranty Deed	Transfer of ownership of the 50-acre site parcel from Harry Cumbaa, as Trustee of the Cumbaa Family Trust 1995, to the Cumbaa Family Trust 1995.	1376	0636
02/01/2013	Warranty Deed	Transfer of ownership of the 125-acre site parcel from Harry Cumbaa, as Trustee of the Cumbaa Family Trust 1995, to the Cumbaa Family Trust 1995.	1376	0637
09/25/2013	Restrictive Covenant	Restrictive covenant between the Cumbaa Family Trust 1995 and FDEP defines shallow ground water and land use restrictions for the two site parcels.	1400	0030

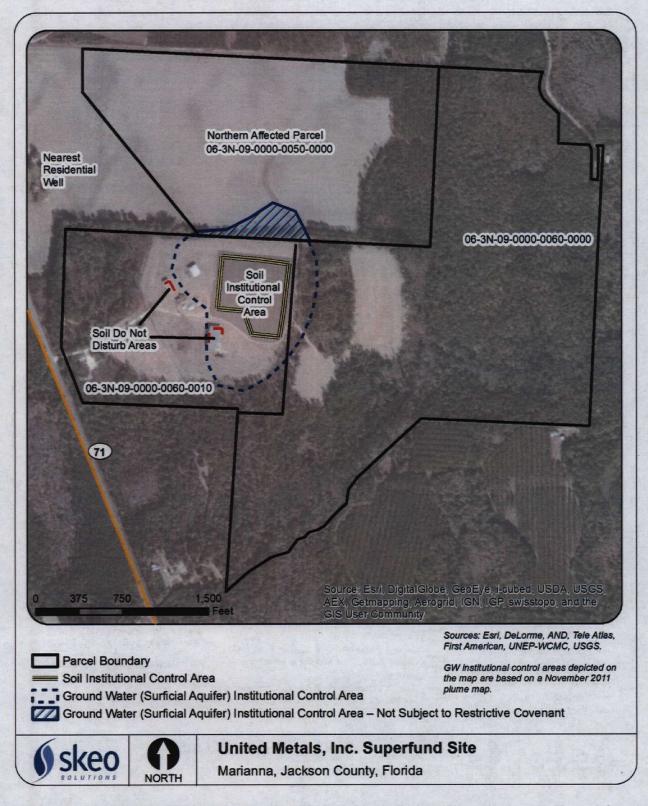

# Table 5: Documents from Jackson County Public Records Office

#### 6.4 Data Review

#### Ground Water

FDEP conducted limited ground water monitoring at the Site in the early 1990s. EPA conducted additional ground water monitoring during the remedial investigation in 2002 and 2003. Regular ground water monitoring at the Site began in 2010 to monitor the effectiveness of the soil remedy.

EPA contractors collected ground water samples from five verification performance monitoring wells (GWVM05 through GWVM09) and 20 additional monitoring wells (MW04/GWMW01, GWMW04 through GWMW18, USTGW01, and MW01 through MW03) (Figure 4). Contractors performed this sampling quarterly between December 2010 and October 2012 and semi-annually thereafter. Samples from shallow wells GWVM05 through GWVM09, located around the monolith, monitor the performance of the containment cell. Initially, EPA analyzed ground water samples for different contaminants based on well type. Beginning in May 2012, all wells were monitored for the same metals. Although trichloroethene (TCE) is a ground water COC, it was eliminated from the sampling program in 2011 because no VOCs had been detected during recent monitoring events. Field measurements were also collected from each well.

For this data review, ground water results were compared to RGs and MNA values (10 times the RG) for seven metals: aluminum, antimony, cadmium, iron, lead, manganese and vanadium.

#### Verification Performance Monitoring

The five verification wells – all shallow and intermediate ground water wells – are located along the perimeter of the soil monolith (Figure 4). All seven ROD-established COCs exceeded RGs at least once in the five verification performance monitoring wells sampled from October 2010 to August 2013; however, the COCs most frequently detected above cleanup goals were manganese, cadmium and aluminum. Well GWMV08, located immediately west of the soil monolith, reported the highest concentrations of all COCs, except for cadmium in GWVM09 (Table H-1).

COC concentrations in most wells have decreased since initial sampling in October 2010, at the end of the soil remedial action. During the July/August 2013 sampling event, only two COCs exceeded RGs: manganese (16,000  $\mu$ g/L in GWVM05) and antimony (7.2  $\mu$ g/L in GWVM06). Manganese in GWVM05 also exceeded the MNA value. Although GWVM08 historically had the highest COC concentrations in verification performance monitoring wells, no COCs exceeded RGs in GWVM08 during the two most recent sampling events in January and July/August 2013(Table H-1). Ground water concentrations are expected to continue to improve because of the soil remedial action and source removals.

An exception to the downward concentration trends was observed for manganese in GWVM05. This well is located along the northern edge of the capped monolith. Manganese concentrations in this well increased from 1,400  $\mu$ g/L in October 2010 to 16,000  $\mu$ g/L in August 2013, with a maximum detection of 20,000  $\mu$ g/L in October 2012.

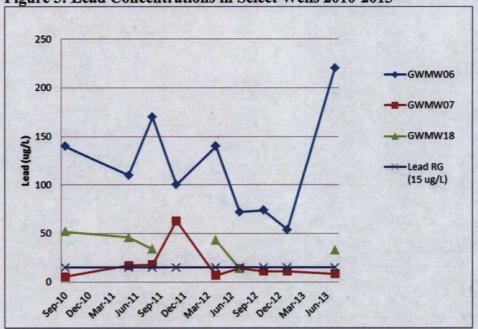

#### Additional Ground Water Monitoring

Twenty additional monitoring wells were sampled between September and October 2010 and July 2013. These wells are located on site and off site. Most of these wells monitor the shallow and intermediate aquifers. Two wells (GWMW14 and GWMW15) monitor the upper Floridan Aquifer. Results are presented in Appendix F. The COCs most frequently detected above RGs in the shallow and intermediate depth aquifer wells between 2010 and 2013 were manganese, cadmium, aluminum and lead. Manganese is the only COC detected above RGs in the Floridan Aquifer wells. Wells with the highest COC concentrations and the most consistent detections above RGs (GWMW07 and GWMW04) are located in ground water with low pH (between 3 and 4), which indicates an acidic environment due to past disposal of battery acid (see Table H-2). Well GWMW04 is located immediately north of the capped monolith. Well GWMW07 is located north of the capped area and immediately south of the northern site boundary (Figure 2). The July 2013 Groundwater Implementation Status Report states that the pH is expected to slowly return to normal over time through the natural buffering capacity of the surrounding ground water and soils, but that it may take decades to fully recover.

#### COC Concentration Trends

To evaluate trends by COC, time series graphs were prepared for aluminum, cadmium, iron, lead, manganese and vanadium in wells that had consistent RG exceedances (Appendix H).

In general, lead concentrations do not show clear trends. However, the data show an increase in lead concentrations in GWMW06 between the January 2013 (54  $\mu$ g/L) and July/August 2013 (220  $\mu$ g/L) sampling events (Figure 5). GWMW06 is located immediately downgradient from the capped monolith.

Trends in manganese concentrations vary by well. Some wells have increasing trends (GWMW11, GWMW13, GWMW15), others have decreasing trends (GWMW14) and others have no trends (GWMW07, GWMW10) (Figure 6). Manganese has been consistently detected above RGs in the two Floridan Aquifer wells (GWMW14 and GWMW15) since sampling began in 2010 (Appendix F). While manganese can occur naturally, the 2005 remedial investigation reported non-detectable background manganese concentrations in site ground water from the surficial aquifer. This suggests that elevated ground water manganese concentrations in the surficial aquifer are likely site-related. Elevated concentrations of manganese in the Floridan Aquifer may or may not be site related.

Figure 5: Lead Concentrations in Select Wells 2010-2013

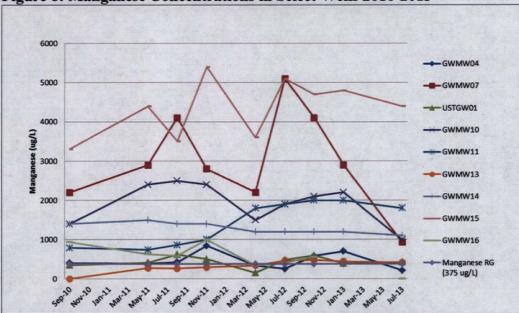

Figure 6: Manganese Concentrations in Select Wells 2010-2013

During the most recent sampling event in July 2013, aluminum, cadmium, lead and manganese were the only COCs detected above RGs. Concentrations of lead in GWMW06 and manganese in Floridan Aquifer well GWMW15 also exceeded their MNA values during the July 2013 sampling event (see Appendix F).

#### Data Review Summary

In general, ground water quality at the Site has improved since the soil remedial action. However, there are localized areas where COC concentrations have increased and COCs exceed MNA criteria. Highly acidic conditions, such as battery acid, will mobilize metals in soil. Battery acid also contains high concentrations of dissolved metals. In the areas showing elevated and increasing COC concentrations, it is possible that those COCs are leaching from the soil to the ground water due to the acidity of site ground water. However, it is common for COC concentrations in ground water to fluctuate early in the MNA process, but ultimately fall below RGs after time allows for the completion of the attenuation process. Continued monitoring will determine if the elevated and increasing COC concentrations are isolated incidents or may require additional attention.

While data indicate an overall decrease in most COC concentrations at most well locations there have been some exceedances in certain wells that will continue to require attention. In July/August 2013, the northern extent of manganese contamination in the surficial aquifer was north of the northernmost monitoring wells, GWMW11 and GWMW13. Both of those wells recently had manganese concentrations above RGs as did both of the Floridan Aquifer wells (GWMW14 and GWMW15). Well GWMW18 is one of the southernmost monitoring wells at the Site and was not sampled in October 2012 or January 2013. Lead concentrations at that well rose from 14  $\mu$ g/L in July 2012 to 33  $\mu$ g/L in July 2013. EPA has determined that the delineation on the southern boundary is adequate and does not require further study. The potentiometric surface indicates that the ground water in the vicinity of GWMW18 flows west toward MW-1. MW-1 does not

have lead above RGs. EPA is also aware of the exceedence of RGs for manganese in the Floridan Aquifer wells and will continue to evaluate if additional Floridan Aquifer wells are needed.

<u>Soil</u>

No new soil data have been collected since implementation of the soil remedy in 2010.

#### 6.5 Site Inspection

On March 27, 2014, Joe Alfano (EPA), Eric Marsh and Claire Marcussen (Skeo Solutions) met with John Sykes (FDEP) and Amber Igoe (TetraTech, FDEP's O&M contractor) at the Site. Joe Alfano and FDEP gave a tour of the Site. The group toured the Site to observe the condition of all remedial components, including site fencing, monitoring wells, the capped area and restored wetland area.

Overall, the Site was well-maintained and the remedy appeared to be in working order. Signs located on fencing throughout the Site clearly marked the presence of a Superfund site. Access to the main former facility area is secured by a locked gate and fence. The capped area is surrounded by another locked gate and fence within the larger fenced area. Site inspection participants observed a small section of damaged fencing around the capped area. One small tree was also observed growing on the cap. The FDEP O&M contractor stated that the tree will be removed during the next mowing.<sup>1</sup> The capped area of the landfill and non-capped area of the Site were well-vegetated. Cap vegetation appeared healthy and well-maintained, with no signs of animal burrowing or surface disruptions. Site inspection participants located and identified all monitoring wells. All wells appeared to be in good condition and were locked at the time of the inspection. Landfill settlement monuments also appeared to be in good condition, with no evidence of cap settlement observed. The remediated wetland area west of the Site and Highway 71 appeared to be in good condition. Wetland vegetation appeared to be healthy. Site inspection participants also observed current land use activities, which include an autoscrapping and roll-off storage container leasing operation. Scrap vehicles, piles of scrap metal and roll-off containers were observed throughout the Site. The capped area is not in use.

As part of the site inspection, Skeo Solutions staff visited the designated site repository, the Jackson County Public Library, located at 2929 Green Street, in Marianna. No site-related documents were on file at the repository.

Appendix D includes a completed Site Inspection Checklist. Appendix E includes photographs taken during the site inspection.

<sup>&</sup>lt;sup>1</sup> The site tenant has since repaired the hole in the fence with more wire. FDEP has since had the capped area mowed twice. The saplings are no longer an issue.

#### 6.6 Interviews

The FYR process included interviews with parties affected by the Site, including the regulatory agencies involved in site activities or aware of the Site. The purpose was to document the perceived status of the Site and any perceived problems or successes with the phases of the remedy implemented to date. The interviews are summarized below. Appendix C provides the complete interviews.

<u>Joe Alfano</u>: Joe Alfano is the EPA RPM for the Site. Mr. Alfano submitted his interview responses on April 2, 2014, via email. Overall, Mr. Alfano has a positive impression of the Site, stating that the cleanup was successful and the remedy is being well-maintained and performing as designed. EPA is not aware of any community concerns regarding the remedy's operations or management, or of any adverse effects on the surrounding community. Mr. Alfano also stated that the institutional controls are in place and adequate.

Joe Gunn: Joe Gunn is the representative for EPA's LTRA contractor, Black & Veatch. Mr. Gunn submitted his interview responses on April 2, 2014, via email. Overall, Mr. Gunn has a positive impression of the Site's cleanup, stating the project was very well planned and allowed for reuse of part of the property. The cleanup met the soil cleanup requirements, with the exception of a few areas under existing building foundations, which have been identified in the Restrictive Covenant. Maintenance is low due to cap design and vegetative cover. While there have been no performance assessments to date, Mr. Gunn believes that the stabilized monolith will last for many years if left undisturbed. The ground water contains a few metals above cleanup goals or FDEP Groundwater Cleanup Target Level (GCTL) limits, but overall the trends seem to show improvement in ground water quality. The pH of the ground water will take several years to stabilize and improve. Mr. Gunn stated that the pH of the ground water may be the cause for some of the metals (solubility) in the ground water. He also stated that under normal pH soil conditions, the metals may be less soluble and mobile. No changes have been required from the original ground water monitoring requirements; ground water is now monitored semi-annually.

John Sykes: John Sykes is FDEP's O&M manager for the Site. Mr. Sykes has a good impression of the project overall but is concerned about the reuse of the Site as an auto salvage and roll off storage business. He noted that one nearby resident also expressed concern about how the site is being reused. Mr. Sykes noted that the monolith appears to be performing well. He thought that ground water concentrations would decrease faster, but EPA continues to monitor it. Mr. Sykes requested that FDEP's Northwest District inspect the on-site business, however staff did not note any significant violations of FDEP rules.

#### 7.0 Technical Assessment

#### 7.1 Question A: Is the remedy functioning as intended by the decision documents?

The review of documents, ARARs, risk assumptions and the site inspection indicate that the remedy is functioning as intended by the site's decision documents. Contaminated soils and sediment were excavated, treated and contained within a capped monolith. Following treatment, soil and sediment were analyzed to make sure they met cleanup goals in the ROD. Confirmatory sampling revealed that contaminant concentrations for treated soil and excavated areas met the Site's cleanup goals at all but a few locations. Soil contamination remains under sections of the foundation/concrete slabs of the former plastics building and office building. However, a restrictive covenant restricts digging and excavation in those areas without prior FDEP/EPA approval to prevent potential contaminant exposure.

The restrictive covenant also restricts the use of ground water from the shallow aquifer for the two on-site parcels and prohibits any activities that could disturb the integrity of the capped monolith without first notifying and obtaining approval from EPA and FDEP. EPA is also coordinating with the Northwest Florida Water Management District to restrict future well placement on the northern property. EPA considers this an adequate institutional control for the ground water plume on the northern property. The cap over the treated soil and sediment prevents potential exposure to COCs in surface soils and sediment with concentrations above appropriate risk levels and helps prevent contaminants from leaching into the shallow ground water below. Additionally, a fence surrounds the capped area, further limiting the potential for exposure to site contaminants.

The on-site potable water well, P-1, is installed in the Floridan Aquifer and can be used by the current site tenant. The Site's remedial investigation determined that the on-site potable ground water wells and the off-site private potable water wells, installed in the Floridan Aquifer, were not impacted by Site contamination. More recent sampling of well P-1 in 2010 did not shown COC concentrations above RGs.

In general, ground water sampling results indicate that ground water quality at the Site has improved since the soil remedial action; this improvement is expected to continue. However, there are localized areas where COC concentrations have increased and areas where COCs still exceed MNA criteria. Continued monitoring of both surficial ground water and the Floridan Aquifer will determine if the elevated and increasing COC concentrations are isolated incidents, or may require additional attention. Data also suggests that the extent of manganese contamination in both the surficial and Floridan aquifers is not fully defined. More information and data is necessary for manganese in the surficial and Floridan aquifers to determine if additional actions are necessary, including monitoring wells and/or institutional controls.

# 7.2 Question B: Are the exposure assumptions, toxicity data, cleanup levels and remedial action objectives (RAOs) used at the time of remedy selection still valid?

The exposure assumptions, toxicity data and RAOs used at the time of remedy selection are still valid. All cleanup levels for soil are still valid, except one: antimony. ARARs used at the time of remedy selection are also still valid. The ground water ARARs have not changed for any of the COCs since the 2006 ROD.

The 2006 ROD did not identify vapor intrusion as a site risk. One of the Site's ground water COCs, TCE, may result in vapor intrusion. However, EPA approved the elimination of TCE from the Site's ground water sampling program in 2011 because no VOCs had been detected during recent monitoring events. The lack of detectable VOC concentrations in site ground water indicates that vapor intrusion does not currently pose a risk to human health.

In 2005, the Site's risk assessment concluded that the Site principally posed a threat to visitors and trespassers through potential exposure to surface soil and sediment. The risk assessment found no risk of contaminant exposure to workers due to the lack of a worker population within the extent of contamination. The cap over the treated soil and sediment prevents exposure to COCs in surface soils above appropriate risk levels and helps prevent contaminant leaching into the shallow ground water below. The excavation and treatment of contaminated wetland sediment and its placement in the on-site monolith prevents exposure to sediment above appropriate risk levels.

The soil cleanup goals were established to prevent leaching to ground water and unacceptable cancer or noncancer risks to residents. Because cancer toxicity values became more stringent for arsenic and a noncancer toxicity value is now available, the protectiveness of the cleanup goals established in the ROD was reviewed. To evaluate the effect of the toxicity value changes on the cleanup goals established in the ROD, the cleanup goals were compared to EPA Regional Screening Levels (RSLs) for direct contact and migration to ground water (Tables K-1 and K-2). The analysis indicates that the cleanup goal for arsenic, based on direct contact, remains valid because the level is equivalent to a residential cancer risk of  $3.44 \times 10^{-6}$ , which falls well within EPA's risk management range of  $1 \times 10^{-6}$  to  $1 \times 10^{-4}$ . The equivalent noncancer hazard index of 0.06 is also well below the noncancer hazard index of 1.0.

The ecological cleanup goals, based on the protection of terrestrial biota for soil and aquatic biota for sediment, applied to the top six inches of soil and sediment. The ecological removal action in the wetland area involved the excavation of the top six inches of soil and sediment, thereby meeting the Site's soil and sediment ecologically-based cleanup goals.

The soil cleanup goals were also compared to the residential Florida soil cleanup target levels (SCTLs) for direct contact and migration to ground water. Although the current SCTL for antimony of 27 mg/kg is lower than the cleanup goal of 31 mg/kg, the selected

remedy of treatment and covering of contaminated soil eliminates the direct exposure pathway. Therefore the soil remedy remains protective.

The ROD did not specify the Florida leachability criteria as the Site's RGs for the protection of ground water; however, the RGs are equal to the Florida criteria. EPA's current soil screening levels for the protection of ground water are lower than the ROD's cleanup goals based on COC migration to ground water (Table K-3). The selected remedy of soil treatment and capping helps prevent the leaching of COCs to ground water at levels above ground water cleanup goals. Routine ground water monitoring will determine the remedy's effectiveness.

# 7.3 Question C: Has any other information come to light that could call into question the protectiveness of the remedy?

No. No other information has come to light that could call into question the protectiveness of the remedy.

#### 7.4 Technical Assessment Summary

The review of documents, ARARs, risk assumptions and the site inspection indicate that the remedy is functioning as intended by the Site's decision documents. Contaminated soils and sediment were excavated, treated and contained within a capped monolith. Following treatment, soil and sediment were analyzed to make sure they met cleanup goals in the ROD. Soil contamination remains under sections of the foundation/concrete slabs of the former plastics building and office building. However, a restrictive covenant restricts digging and excavation in those areas without prior FDEP/EPA approval to prevent potential contaminant exposure. In general, ground water sampling results indicate that ground water quality at the Site has improved since the soil remedial action; this improvement is expected to continue. Institutional controls restrict any site activities that may disturb the integrity of the capped monolith area and restrict the use of surficial ground water on the Site. Additionally, coordination between EPA and the Northwest Florida Water Management District restricts future well placement on the northern property.

There are localized areas where COC concentrations have increased and areas where COCs still exceed MNA criteria. Continued monitoring of both surficial ground water and the Floridan Aquifer will determine if the elevated and increasing COC concentrations are isolated incidents, or may require additional attention. Data also suggests that the extent of manganese contamination in both the surficial and Floridan aquifers is not fully defined. More information and data is necessary for manganese in the surficial and Floridan aquifers to determine if additional actions are necessary, including monitoring wells and/or institutional controls.

## 8.0 Issues

Table 7 summarizes the current site issues.

#### Table 7: Current Site Issues

Issue	Affects Current Protectiveness?	Affects Future Protectiveness?
The extent of manganese contamination in surficial ground water is not fully defined.	No	Yes
The extent of manganese contamination in the Floridan Aquifer is not fully defined.	No	Yes

41

### 9.0 Recommendations and Follow-up Actions

Table 8 provides recommendations to address the current site issues.

Issue	Issue Recommendation / Party Oversight Milestone Follow-Up Action Responsible Agency Date		Affects Protectiveness?			
		· · · · · · · · · · · · · · · · · · ·		Current	Future	
The extent of manganese contamination in surficial ground water is not fully defined.	Further evaluate manganese in the surficial ground water to determine if additional monitoring wells and institutional controls are needed.	EPA	EPA and State	10/14/2017	No	Yes
The extent of manganese contamination in the Floridan Aquifer is not fully defined.	Further evaluate manganese in the Floridan Aquifer to determine if additional monitoring wells and institutional controls are needed.	EPA	EPA and State	10/14/2017	No	Yes

**Table 8: Recommendations to Address Current Site Issues** 

The following item, though not expected to affect protectiveness, warrants additional follow-up:

• Verify that site information is properly maintained and accessible in the site repository.

#### **10.0 Protectiveness Statement**

The remedy at the Site is protective of human health and the environment in the short term. Contaminated soils and sediment were excavated, treated and contained in a capped monolith. The cap prevents potential exposure to COCs in surface soils and sediment and helps prevent contaminants from leaching into the ground water below. Additionally, institutional controls protect the integrity of the monolith and further limit the potential of contaminant exposure by prohibiting digging in areas of remaining soil contamination under building foundations and restricting ground water use. In general, ground water sampling results indicate that ground water quality at the Site has improved since the soil remedial action; this improvement is expected to continue. However, in order for the remedy to be protective in the long term, more information and data is necessary for manganese in the surficial and Floridan aquifers to determine if additional actions are necessary, including monitoring wells and/or institutional controls.

# 11.0 Next Review

The next FYR will be due within five years of the signature/approval date of this FYR.

#### **Appendix B: Press Notice**

#### The U.S. Environmental Protection Agency, Region 4 Announces the First Five-Year Review for the United Metals, Inc. Superfund Site, Marianna, Jackson County, Florida

**Purpose/Objective:** EPA is conducting a Five-Year Review of the remedy for the United Metals, Inc. Superfund site (the Site) in Marianna, Florida. The purpose of the Five-Year Review is to make sure the selected cleanup actions effectively protect human health and the environment.

Site Background: The 180-acre Site is surrounded by farmland, woods and wetlands. The Site includes about 24 acres where a battery reclaiming facility operated from 1979 until 1991. Facility operations included reclaiming lead from batteries, shredding the battery cases and sending the materials off site for further processing. Following the neutralization of liquid battery wastes in concrete basins, site operators discharged the waste to an unlined holding pond. Facility operations contaminated soil, sediment and ground water with various metals, including lead, cadmium and antimony. EPA placed the Site on the Superfund program's National Priorities List (NPL) in April 2003.

**Cleanup Actions:** EPA selected the Site's remedy in the Site's September 2006 Record of Decision (ROD) and updated the remedy in an Explanation of Significant Differences (ESD) in 2010. The final remedy consisted of monitored natural attenuation (MNA) for contaminated ground water and solidification/stabilization for contaminated soils. The remedy also included a cap for treated soils, removal of contaminated structures and wetlands restoration. EPA completed two short-term cleanups, or removal actions, at the Site in 1996 and 2006. Construction of the long-term remedy started in 2009 and finished in September 2011. The remedy also calls for ground water and land use restrictions. Ground water monitoring is ongoing.

**Five-Year Review Schedule:** The National Contingency Plan requires review of remedial actions that result in any hazardous substances, pollutants or contaminants remaining at the Site above levels that allow for unlimited use and unrestricted exposure every five years to ensure the protection of human health and the environment. The first Five-Year Review for the Site will be completed by October 2014.

**EPA Invites Community Participation in the Five-Year Review Process:** EPA is conducting this Five-Year Review to evaluate the effectiveness of the Site's remedy and to ensure that the remedy remains protective of human health and the environment. As part of the Five-Year Review process, EPA staff is available to answer any questions about the Site. Community members who have questions about the Site or the Five-Year Review process, or who would like to participate in a community interview, are asked to contact:

Joseph Alfano, EPA Remedial Project Manager	L'Tonya Spencer, EPA Community Involvement
Coordinator	
Phone: (404) 562-8933	Phone: (404) 562-8463   (877) 718-3752 (toll-free)
Email: alfano.joe@epa.gov	Email: spencer.latonya@epa.gov

Mailing Address: U.S. EPA Region 4, 61 Forsyth Street, S.W., 11th Floor, Atlanta, GA 30303-8960

Additional site information is available at the Site's local document repository, located at the Jackson County Public Library, 2929 Green Street, Marianna, Florida 32446, and online at: http://www.epa.gov/region4/superfund/sites/npl/florida/unitmfl.html.

		-		

#### Interview Category: EPA Remedial Project Manager

- What is your overall impression of the project, including cleanup, maintenance and reuse activities (as appropriate)? The cleanup was successful and the remedy is being well maintained.
- 2. What have been the effects of this Site on the surrounding community, if any? I am not aware of any adverse effects on the surrounding community.
- Are you aware of any complaints or inquiries regarding site-related environmental issues or remedial activities since the implementation of the cleanup?
   I am not aware of any complaints regarding remedial activities since implementation of the cleanup.
- 4. What is your assessment of the current performance of the remedy in place at the Site? The remedy is performing well.
- 5. Are you comfortable with the status of the institutional controls at the Site? If not, what are the associated outstanding issues? The institutional controls are in place and adequate.
- Are you aware of any community concerns regarding the Site or the operation and management of its remedy? If so, please provide details.
   I am not aware of any community concerns regarding the remedy's operations or management.
- Do you have any comments, suggestions or recommendations regarding the management or operation of the Site's remedy? No.

United Metals, Inc. Superfund Site	<b>Five-Year Review Interview Form</b>
Site Name: <u>United Metals, Inc.</u>	EPA ID No.: <u>FLD098924038</u>
Interviewer Name:	Affiliation:
Subject Name: <u>Joe Gunn</u>	Affiliation: Black & Veatch
Subject Contact Information: <u>1120 Sanctuary</u>	Parkway Suite 200 Alpharetta, Ga 30009
Time:	Date: April 2, 2014
Interview Location: Office	
Interview Format (circle one): In Person	Phone <u>Email</u> Other:

Interview Category: EPA's LTRA Contractor

1. What is your overall impression of the project, including cleanup, maintenance and reuse activities (as appropriate)?

This was a very well-planned project, met all the soil cleanup requirements except a few areas that may be under existing building foundations (which have been identified in the Restrictive Covenants). Maintenance is low due to cap design and vegetative cover. The site remedy allowed for the reuse of the property with the exception of the monolith area (treated soils).

- 2. What is your assessment of the current performance of the remedy in place at the Site? There have been no performance assessments to date; the stabilized monolith will last for many years if left undisturbed. The performance data taken on the stabilized material daily during production and construction of the monolith met all geotechnical and chemical performance goals established for the project.
- 3. What are the findings from the ground water monitoring data? What are the key trends in contaminant levels that are being documented over time at the Site? The ground water does contain a few metals above goals or FDEP GCTL limits, but overall, the trends seem to show improvement in ground water quality due to the soil remediation efforts and monolith capped area protecting underlying soils and ground water. The pH of the ground water will take several years to stabilize and improve, and may be the cause for some of the metals (solubility) in the ground water. Under normal pH conditions in the soils, the metals may be less soluble and mobile.
- 4. Have there been any significant changes in ground water monitoring requirements? If so, do they affect the protectiveness or effectiveness of the remedy? Please describe changes and impacts.

No changes have been required from original ground water monitoring requirements. The first few years were quarterly monitoring; now under semi-annual monitoring.

5. Please describe any additional activities related to the ground water remedy you are performing.

There are no additional activities planned for the ground water at this time.

- 6. Have there been opportunities to optimize ground water monitoring or related activities? Please describe changes and any resulting or desired cost savings or improved efficiencies. No response.
- Do you have any additional comments, suggestions or recommendations regarding on-going ground water monitoring or related activities at the Site? No response.

United Metals, Inc. Superfund Site	Five-Year Review Interview Form
Site Name: <u>United Metal, Inc.</u>	EPA ID No.: FLD098924038
Interviewer Name:	Affiliation:
Subject Name: <u>John Sykes</u>	Affiliation: <u>FDEP</u>
Subject Contact Information: (850) 245-8960	John.Sykes@dep.state.fl.us
Time: <u>10:15 am</u>	Date: <u>6/24/14</u>
Interview Location: <u>via e-mail</u>	
Interview Format (airole one). In Person	Phone Mail Other: F-mail

Interview Category: State Agency – FDEP

- What is your overall impression of the project, including cleanup, maintenance and reuse activities (as appropriate)?
   Generally good, but concerned about reuse as an auto salvage business & rolloff storage.
   Will continue to monitor this closely.
- 2. What is your assessment of the current performance of the remedy in place at the Site? Monolith appears to be performing well, but thought that groundwater concentrations would decrease faster. EPA is monitoring this, however.
- Are you aware of any complaints or inquiries regarding site-related environmental issues or remedial activities from residents in the past five years?
   Some concern from one nearby resident about the reuse as an auto graveyard. No actual complaints.
- 4. Has your office conducted any site-related activities or communications in the past five years? If so, please describe the purpose and results of these activities. Aside from routine O&M visits, the one call described in #3, above, and routine communications with EPA and our O&M contractor, no.
- 5. Are you aware of any changes to state laws that might affect the protectiveness of the Site's remedy? No.
- Are you comfortable with the status of the institutional controls at the Site? If not, what are the associated outstanding issues? Yes. No problems with ICs that I am aware of.
- 7. Are you aware of any changes in projected land use(s) at the Site? Not since auto salvage & rolloff business relocated there.
- 8. Do you have any comments, suggestions or recommendations regarding the management or operation of the Site's remedy?

No. Will continue routine O&M and have requested DEP Northwest District to inspect auto salvage & rolloff business – they did not note any significant violations of DEP rules.

	X. OTHER REM	EDIES		
If there are remedies applied at the site and nature and condition of any facility associa	ted with the remedy	. An example would be soil		
	OVERALL OBSE	RVATIONS	<b>利用的资料</b> 在1991年1月1日	
A. Implementation of the Remedy				
The remedy at the Site is being implemented as required by the Site's decision documents. Contaminated soils and sediment were excavated, treated and contained in a capped monolith. The cap prevents potential exposure to COCs in surface soils and sediment and helps prevent contaminants from leaching into the ground water below. Additionally, institutional controls protect the integrity of the monolith and further limit the potential of contaminant exposure by prohibiting digging in areas of remaining soil contamination under building foundations and restricting ground water use. In general, ground water sampling results indicate that ground water quality at the Site has improved since the soil remedial action; this improvement is expected to continue. While there are localized areas where ground water COC concentrations have increased and areas where COCs still exceed MNA criteria, continued monitoring will ensure the continued protectiveness of the remedy.				
B. Adequacy of O&M				
Overall, the site is well maintained. A small section of damaged cap fence needs to be repaired, and a tree growing on the cap needs to be removed. The change in ground water monitoring frequency from quarterly to semi-annually provides a significant cost savings, as evidenced by comparing O&M costs for 2012 and 2013.				
C. Early Indicators of Potential Remedy Problems				
There are no early indicators of potential re-	emedy problems.		学们的" <u>新</u> 行"的新闻。	
D. Opportunities for Optimization				
There are no known opportunities for optim	nization.			

## **Appendix E: Photographs from Site Inspection Visit**

Locked gate to enter disposal cell area.

Entrance to site off of Highway 71.

View of vegetated cell, looking north to an agricultural area.

View looking southwest of cell; abandoned building on left and improved office building on right.

Secure monitoring well MW-04/GWMW-01.

Small damaged section of fence that surrounds the capped area.

View of vegetative cover on cell and one of four settlement markers.

Scrap metal operations on the slab of the former one-story building.

Scrap metal located in southwest corner of the Site.

Junk cars parked outside of capped area.

On-site scrap metal storage.

Borrow area 3 located southwest of the Site, filled with water.

Vegetative cover on the restored wetland.

### **Appendix K: Cleanup Goal Review**

COC	Soil Cleanup Goal (mg/kg) <sup>a,b</sup>	Residential Soil Cancer RSL (mg/kg) <sup>c</sup>	Residential Soil Non-Cancer RSL (mg/kg)	Residential	
				Risk	Hazard Index
Antimony	31	NA	31	NA	1.00
Arsenic	2.1	0.61	34	3.44E-06	0.06
Iron	23,400	NA	55,000	NA	0.43
Manganese	3,500	NA	NA	NA	NA
Lead	400	400 <sup>d</sup>	400 <sup>d</sup>	NA	NA
	3.44 x 10 <sup>-6</sup>	1.49			

### Table K-1: Soil Cleanup Goals and Residential RSLs

Notes:

a. Obtained from 2006 ROD.

- b. Based on residential exposures and a target cancer risk of 1 x 10<sup>-6</sup> for carcinogens and a noncancer hazard index of 1.0.
- c. RSLs for residential exposure obtained from EPA's November 2013 RSL table http://www.epa.gov/reg3hwmd/risk/human/rb-concentration\_table/Generic\_Tables/index.htm
- d. EPA's Office of Solid Waste and Emergency Response recommends that a soil lead level less than 400 mg/kg is generally safe for residential use.

The cancer risks were calculated using the following equation, based on the fact that RSLs are derived based on 1 x 10<sup>-6</sup> risk:

Cancer risk = (Soil Cleanup Level  $\div$  Soil Cancer RSL)  $\times 10^{-6}$ 

Non-cancer hazard index was calculated using the following equation:

Hazard index = (Soil Cleanup Level ÷ Soil Non-cancer RSL)

### Table K-2: Soil Cleanup Goals and Florida SCTL

COC	Soil Cleanup Goal (mg/kg) <sup>a</sup>	FL Residential Soil SCTL (mg/kg) <sup>b</sup>		
	Direct Contact
