Phytoextraction: using the sun's energy to extract water and contaminants

- Stabilise polluted sites and prevent leaching
- Break-down some toxic chemicals in the soil
- Remove heavy-metals

Generic pros and cons of phytoextraction

- Low cost
- High public appeal
- Permanent
- Leaves site fertile
- Can involve local communities
- May generate a profit off contaminated land
- Limited to areas that support plant-growth
- Long time-frame
- Most effective on surface contamination
- Unsuitable for rapid cleansing

When should phytoextraction be used?

- Most cost-effective long term strategy
- Satisfies environmental legislation

Major drawback of phytoextraction in the commercial environment

- Unlike other land-treatment technologies, the cost and performance of phytoextraction on a given site can be difficult to predict.
- Phytoextraction is very sensitive to
 - climate
 - chemical, physical and biological properties of the substrate.
 - local ecosystem

AIM:

To create a Phytoextraction Decision Support System (Phyto-DSS) that predicts performance and cost of phytoextraction.

•Climate

Phyto-DSS

•Plant water-use and growth parameters

•Plant contaminant-uptake parameters

•Substrate properties affecting water movement and contaminant solubility

•Cost over time of phytoextraction compared to other technologies or inaction

The process of phytoextraction

$$M(t) = \int_0^{z_R} \int_0^t R(t', z) T(t') C(t'z) \phi(C(t'z)) dt dz$$

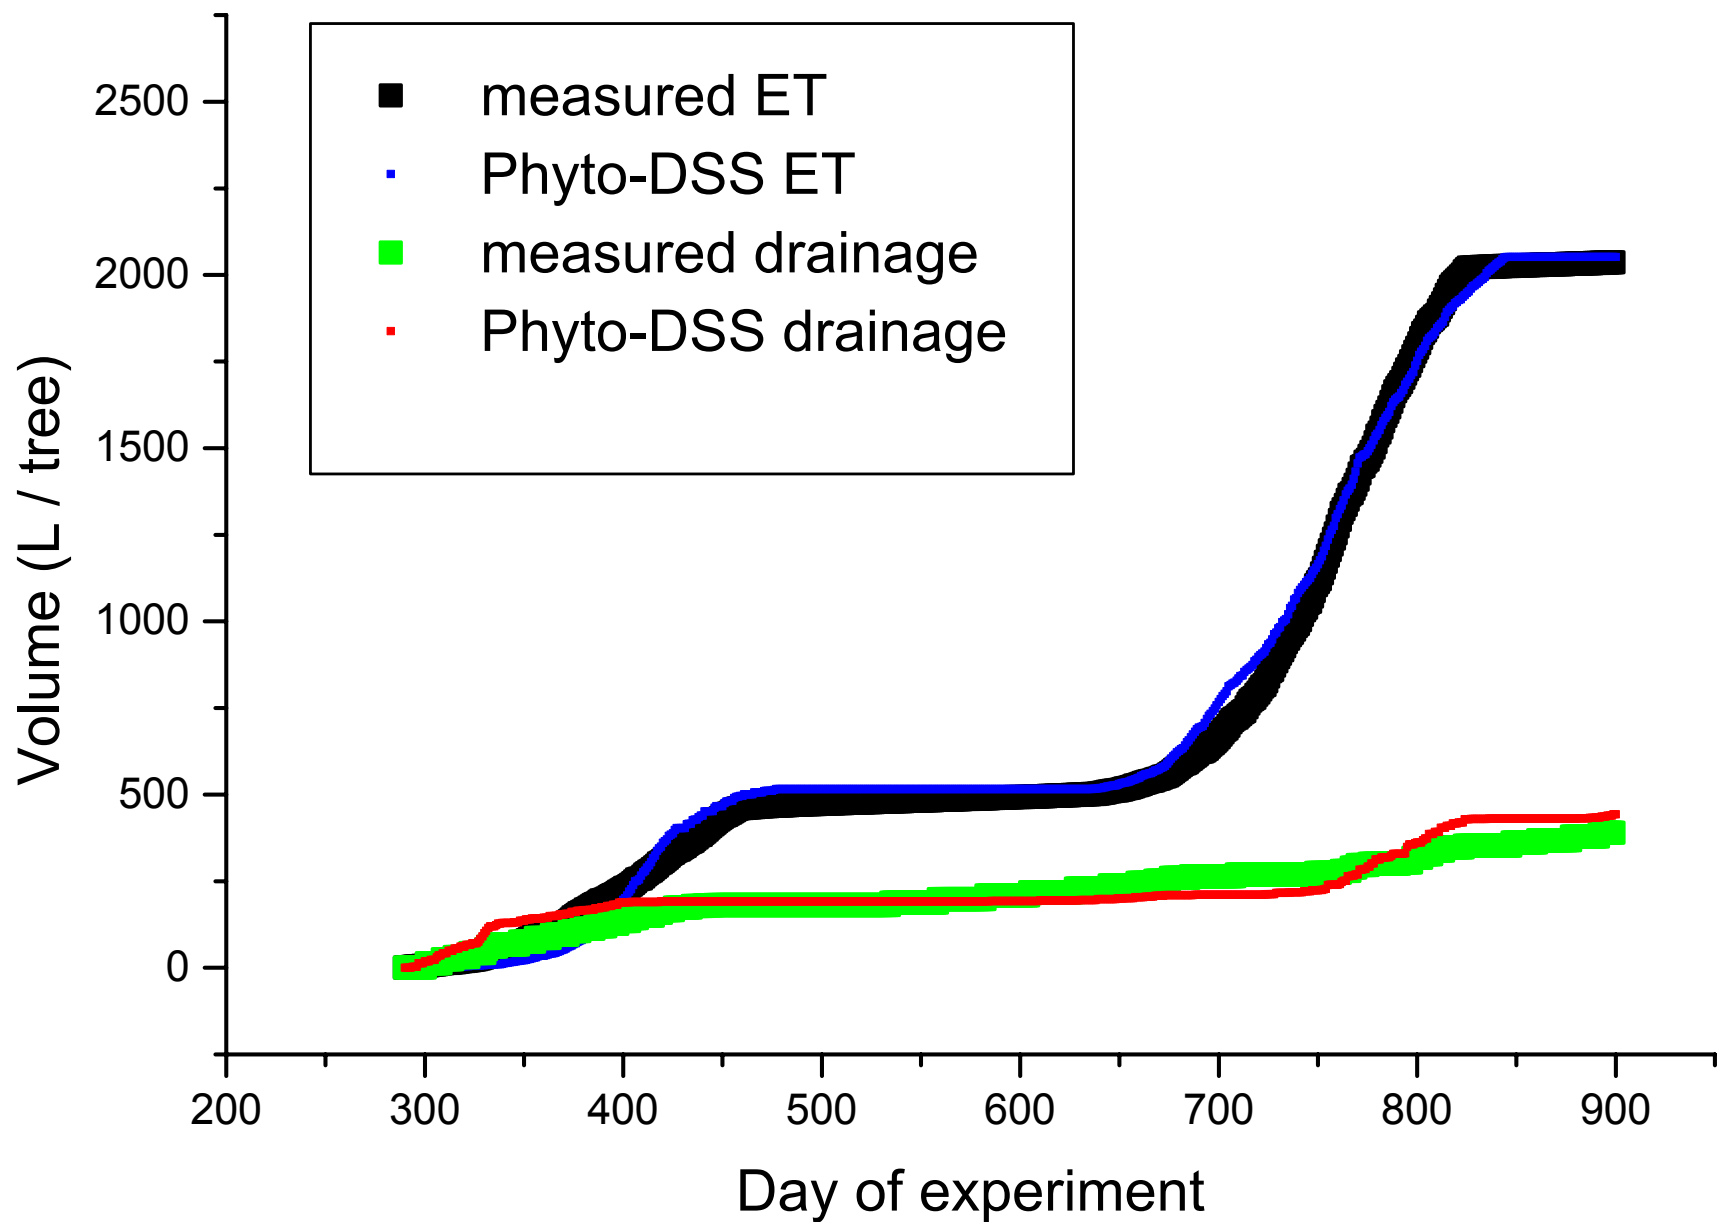

Phytoextraction in action: contaminated sawdust

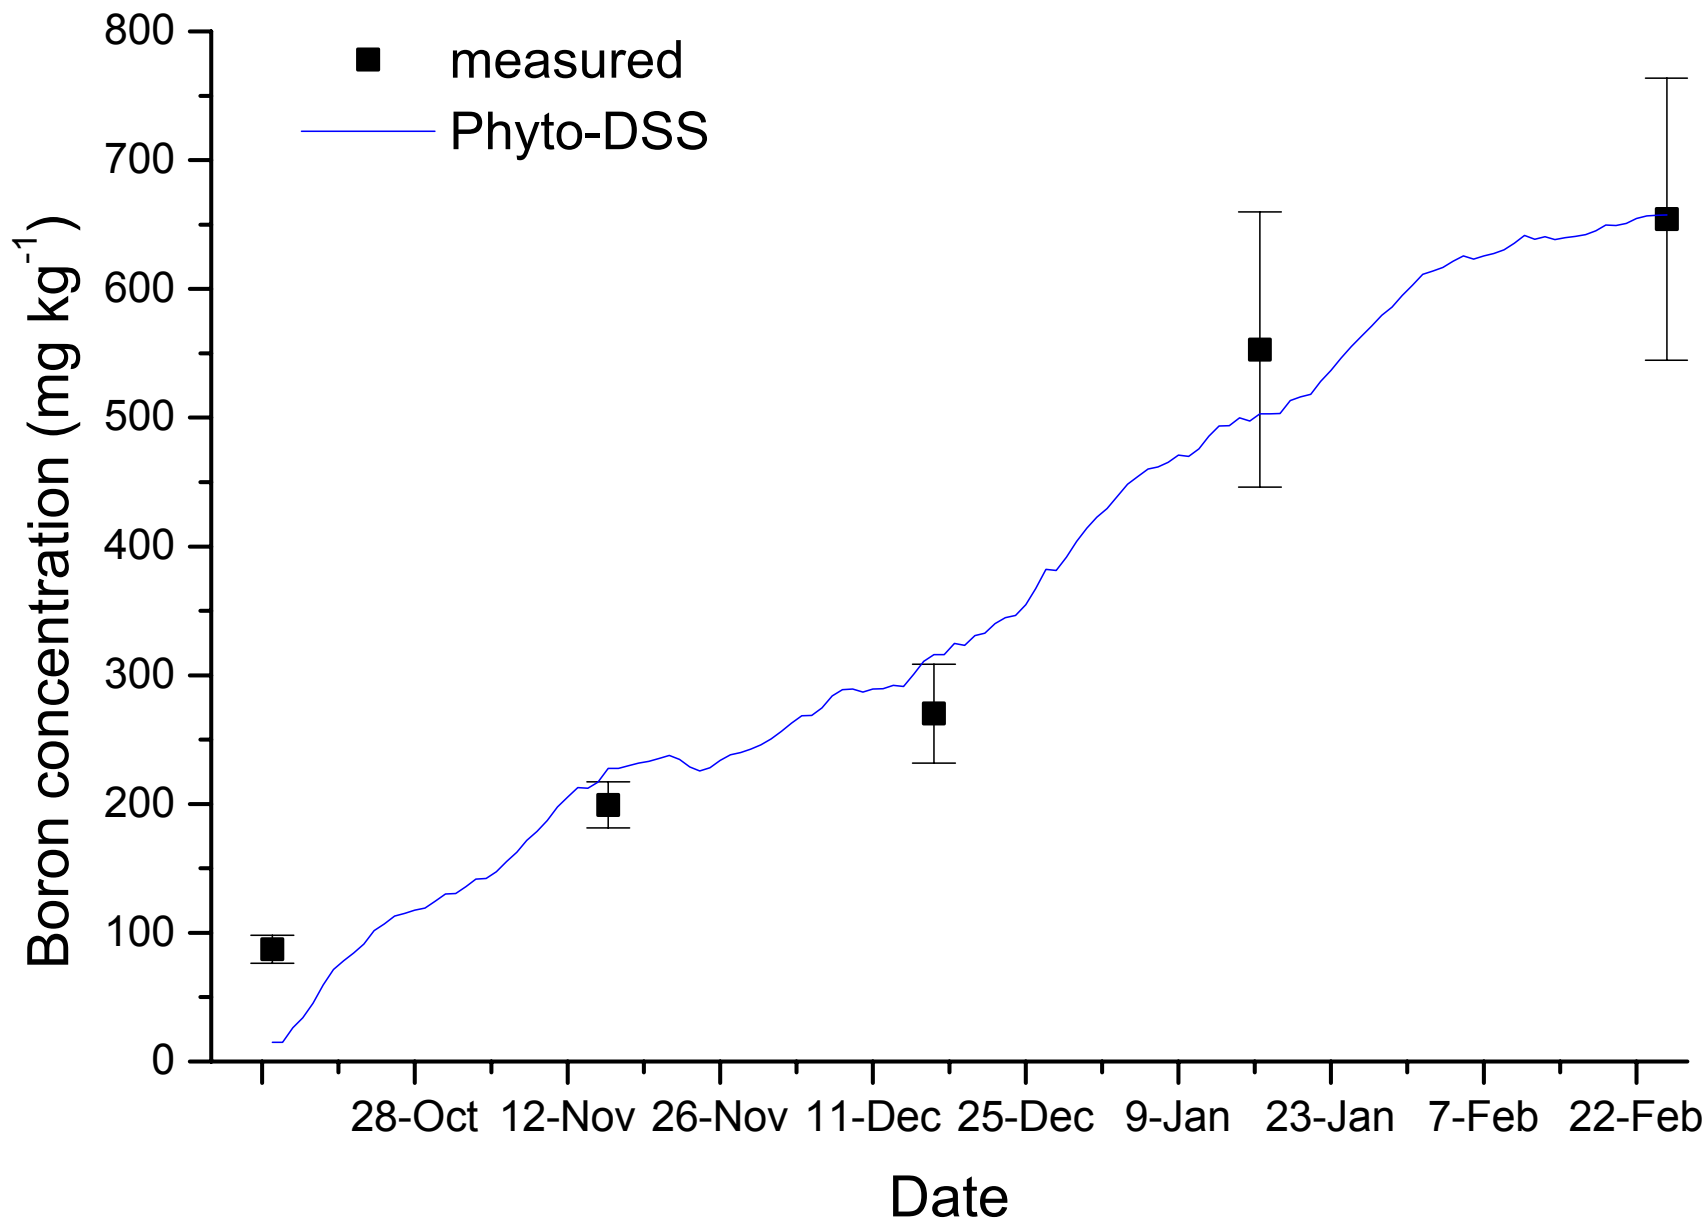

- A 5ha, 15m deep pile of sawdust leaching unacceptable amounts of boron into local waterways
- The Regulatory Authority demanded a US\$ 700,000 capping of this site

Using the correct varieties and soil amendments is essential....

Assessment of phytoextraction at Kopu

- Phytoextraction satisfies environmental legislation on this site
- The total cost of phytoextraction over a ten-year period will be US\$ 170,000 compared to capping at US\$ 950,000
- Selective coppicing will allow B to be removed from the site
- Harvested material could be used as an organic B-rich mulch on nearby avocado orchards that are deficient in B

Assessment of gold phytomining

- Most effective on small 'orphan sites' where conventional extraction is uneconomic
- Can be effectively combined with the rehabilitation of the site
- Timing of amendment addition is critical
- Highly sensitive to the price of gold

Conclusions

- Modelling can be used to predict the appropriateness of phytoextraction
- Accurate site assessment is essential
- Science costs are part of phytoextraction
 - Correct species / variety
 - Substrate amendments
 - Irrigation regime
